Miscellaneous Papers.—Among the papers and addresses which cannot be conveniently classified under any of the above headings are Sir James Paget's address on John Hunter; a paper on re-infusion of blood in primary and other amputations, by Dr. John Duncan; and a case in which transfusion was performed four times, by Mr. Cotterill; a case of amputation of the arm and scapula for ossifying sarcoma, recorded by Mr. Bilton Pollard from the practice of Mr. Christopher Heath, and a similar case by Mr. E. A. Maling; a paper on the surgical treatment of certain tumours of the neck, by Mr. F. B. Jessett; a case in which an enormous fibrocystic tumour was removed from the parotid region, by Surgeon S. J. Rennie; a clinical lecture on cancer of the breast, by Mr. Edmund Owen; a paper by Mr. William Adams on chronic rheumatic arthritis; an address on some points regarding acute rheumatism requiring investigation, by Dr. Stephen Mackenzie; notes of a case of parturition complicated by acute rheumatism and endocarditis, ending in recovery, by Dr. J. E. Squire.

EDITORIAL ARTICLES.

NUMEROUS editorial articles, written, as a rule, by special contributors in various parts of the kingdom, and dealing with a great variety of subjects, have been published during the year.

The British Medical Association.—The Meeting at Brighton; Honours from the Association; The British Medical Association and the BRITISH MEDICAL JOURNAL—Retrospect and Prospect; The Work of the Sections at the Annual Meeting; The Meeting of the British Medical Association in Dublin, 1887.

Recent or Pending Legislation.—Five articles on the Medical Acts Amendment Bill, 1886; The Lunacy Acts Amendment Bill, 1886, in the House of Lords; The Lord Chancellor's Amendments to the Lunacy Acts Amendment Bill; The Recent Cases in Lunacy; Insane Convicts; The Burgh Police and Health (Scotland) Bill; The Delays of Sanitary Legislation.

The General Medical Council.—Two articles on the work of the General Medical Council; two articles on the Election of Direct Representatives, and two others on the State of the Poll.

The London Colleges.—The Presidency of the Royal College of Physicians of London; The Conjoint Scheme and Medical Education; The Society of Apothecaries and its Licentiates; A Ceremony and its Moral; The Art of Delay at the College of Surgeons; The Council of the Royal College of Surgeons; The Coming Meeting at the Royal College of Surgeons; The Meeting of the College of Surgeons and its Results; Mr. Erichsen's Pamphlet on the Members' Franchise; Who is to stop Unqualified Practice? A Grave Question for the Profession and the Colleges; The Colleges of Physicians and Surgeons and the Society of Apothecaries: a Grave Public and Professional Question; The General Practitioners and the Colleges: a Vital Question for the Profession; A New Order of General Practitioners; The Members,

Fellows, and Council of the College of Surgeons: A Constitutional and Historical Study; The Party of Privilege at the College of Surgeons: a Legal Study; The Status and Rights of the Members of the College of Surgeons; The Circular from the Council of the Fellows of the College of Surgeons.

Medical Education.—The Introductory Addresses; the Teaching of the Preliminary Sciences; Clinical Teaching and Clinical Teachers; Clinical Instruction at the Infectious Hospitals; Certificates in Psychological Medicine; Medical Student Life in London; Medical Students and Athletics; Preliminary Education; Changes in the Examinations and Medical Schools; Opening of the Medical Schools; Discipline of Medical Students in London; The Oxford Medical School; The Present Position of the Medical Schools in London; Resident Colleges at Medical Schools; Medical Degrees and Direct Representation; The Title of Doctor for Doubly-qualified Practitioners; two articles on The Reform of the University of London; A Medical Degree for London Students: by Whom and to Whom shall it be granted?; A "Teaching University for London;" The Proposed Medical University.

Physiology and Anatomy.—The Physiology of Sleep; The Dual Action of the Brain; Recent Researches on the Physiology of the Brain; The Relations of Size between the Lungs and Bronchi; On the Position in Nutrition of the various Classes of Food-stuffs; The Chemical Formation of Hard and Soft Tissues; Dr. Wooldridge's Recent Researches on Coagulation of the Blood; Albuminuria in Health; The British Association for the Advancement of Science.

Pathology.—Sir Erasmus Wilson's Legacy to the College of Surgeons; The Erasmus Wilson Lectures; Evolution in Pathology; The Advance of Pathological Photography; Photography in Pathology; Leprosy; The Transmission of Tuberculosis; Scarlet Fever from the Cow; Protective Inoculation; Abnormal Development of the Male Breast.

Medicine.—The Address in Medicine; The Nomenclature of Medicine; The Limits of Exact Knowledge in Medicine; Fallacies of Observations; Dr. Latham's Croonian Lectures; The Tests for Albumen in Urine; Unsettled Problems about Pneumonia; The Lesson of the Epidemic of Hydrophobia; Cauterisation in Hydrophobia; The Prophylaxis of Phthisis; Cold and Phthisis; Damp and Diphtheria; Professional Responsibilities.

Surgery.—The Address in Surgery; The Address in the Section of Surgery; Tumours of the Spermatic Cord; Problems in Syphilis; Dentistry and the State; The Minor Prophets of Surgery; Peritoneal Surgery; Enucleation of the Eyeball; Recent Experiments on the Production of Sympathetic Ophthalmia; On Lesions of the Cornea following the Instillation of Cucaine; Replacement of a Lost Eye.

Obstetrics.—Abdominal Palpation in Obstetrics; Comparative Obstetrics.

Therapeutics.—The Remote Effects of Remedies; The Connection between Chemical Constitution and Physiological Action; The Rightful Claimants; Respiratory Therapeutics; Terebene and its Derivatives; Iodide of Sodium *versus* Iodide of Potassium; Two New Hypnotics; Balneo-therapeutics; Mistakes in Dispensing; The Use and Abuse of Tea; Our Colonial Sanatoria.

Public Health.—The Address in Public Medicine; Sir Spencer Wells on Public Health; The Value of the Biological Test for Potable Waters; Registration of Sanitary Diplomas; Sanitary Plumbing; Practical Sanitation; The Regulation of Dairies; The Reform of Local Government; The New President of the Local Government Board; The New Appointments at the Local Government Board; Artisans' Houses fit for Habitation; Coroners and *Post Mortem* Examinations; Futile Inquests; Public Kitchens; Ships' Surgeons and Ships' Passengers; Unhealthy Health-Resorts; Health-Resorts; The Subsoil and Well-Waters of Rome; Cholera in Europe; The Cholera in Italy; On the Relation between the Water-Supply and the Prevalence of Cholera in Spain in 1885; Surgeon-General Beatson on Cholera.

Army and Navy Medical Services.—The Army Medical School; The Army Medical Staff; Ought Army-Surgeons to engage in Private Practice? Position of Brigade-Surgeons, Army Medical Service in India; Dr. Quain's Address at Netley; Small-pox in the Army and Navy; Civil Hospitals in India.

Social Questions within the Profession.—The Duties of Consultants; Consultants and General Practitioners; Mortality in the Medical Profession; Two Articles on Self-Help in the Medical Profession; The Abuse of Medical Charities; The Quality of Out-Patient Practice; Reform in the Treatment of the Sick Poor; The General Practitioner and the Poorer Classes; Medical Fees under the Labourers' Ireland Act; End of the Eastern Hospitals Scandal; Medical Officers of Schools, their Duties and Uses; The Liverpool Hospital for Women, and the Report of the Committee of Inquiry upon the Operations Performed Therein.

General Social Questions.—The President's Address; The Wear and Tear of Modern Life; The Long Winter; Health in Winter; The *Malaise* of Spring; Birthday Honours to Medical Men; The Annual Exodus to the Seaside; The Medical Aspects of Continental Tours; The Bartlett Case; Automatic Homicide; The Death of the King of Bavaria; A Candidate for a Drunkard's Retreat; The Truth about Alcohol; The Growth of Temperance.

SOCIETIES.

The Royal Medical and Chirurgical Society during 1886.—The Royal Medical and Chirurgical Society has published sixty-nine volumes of *Transactions*, and has by no means exhausted itself. Of late many younger flourishing and friendly rivals have grown up round it, who have attracted to themselves a very fair share of the new work that is being continually offered to the world by the growing energy of English medicine and surgery. A generation ago, its discussions and published volumes offered almost the only considerable collection of the results of English observation. Now these are more widely spread, and almost every branch of practice, and method of study has its Society and Transactions, and the total mass is, perhaps, ten times what it was. Still, the last year's work, brought forward at the Medical and Chirurgical Society, shows a solid value which very fully maintains its reputation, and will stand the wear of time. If an essay is accurate and complete, it does not always lead to such easy discussion or brisk repartee as a case related with a touch of partisanship or a tendency to doubtful inferences. Among the productions that find their way, as a rule, either to the Royal Society or the Medical and Chirurgical Society, are the careful essays on experimental research, of which there are not too many in England at present. Most of the best, notably Dr. Ferrier's and Mr. Victor Horsley's, have naturally fallen to the Royal Society, but among those that have come to the Medical and Chirurgical Society during the past year there is to be noted a clear and elaborate experimental inquiry by Mr. Ballance and Mr. Edmunds on the ligation of the large arteries in their continuity, which goes to show that, in some animals certainly, and in man very probably, the old doctrine that, in tying an artery, it was necessary to rupture the internal coats to secure occlusion is incorrect, and, further, that such rupture is neither necessary nor advisable. This revision of doctrine, or, at least, of practice, hardly as yet meets with the approval of the most experienced surgeons; but though the question may be still undecided, a settlement is greatly advanced by this paper. The work of Dr. Paul Chapman on *Cardiography* and of Mr. Sedgwick on the *Chemical Pathology of the Respiration in Cholera*, touch on more difficult points, and lead to less definite conclusions. The lengthy experiments by Mr. Gostling to show the increase in the proportion of white corpuscles to red in the blood during the process of suppurative but not serous inflammation, show how immense is the region yet unexplored in that most vital fluid, the blood. The inquiry has to do almost entirely with figures, and it is a pity that there are so many mistakes in arithmetic which must be more than printers' errors. Of the complete historical monographs which form a very valuable part of the *Transactions*, the most remarkable was that of Mr. F. Treves on what he proposed to call Richter's hernia, or partial enterocele, which was laid before the Society very lately, and can hardly be discussed in full before its publication, in a more complete form, in the *Transactions* of next year. An interesting but less historical companion monograph was that by Mr. Lockwood on a kindred subject, viz., encysted and infantile hernia. Dr. Champneys furnished a very complete account, in part historical, of the development of mammary functions in the skin of lying-in women, which is full of interest to the inquirer as to the origin of the human organism as we see it now. It tends to show that the sebaceous follicles of the skin are capable of furnishing a true mammary secretion, and that the true origin of the breast is from a highly-specialised aggregation of highly-specialised sebaceous follicles. Dr. Creighton's hypothesis, however, of the close analogy of the supernumerary axillary breasts to the developments of skin follicles found in the dog, has, perhaps, as much or even more to be said for it. Of the papers essentially statistical, the most elaborate, perhaps, was one by Dr. William Ogle on the mortality of the medical profession, a subject which can hardly help having some interest for all. A medical man's life in prognosis is not so bad as a brewer's or a publican's; there is just that to be said for it, but not much more. It is about as bad as a quarryman's, with his dangerous blasting work to do; but worse than a barrister's, and about twice as bad as a clergyman's. As to danger from infectious diseases, medical men die

very much less (one to five) than their neighbours of small-pox, because they know the value of the prophylactic, vaccination; but from scarlet fever, diphtheria, and typhus, where there is no prophylactic, they die much more frequently than other men. A statistical paper by Dr. Angel Money, on some points in pneumonia, especially the relation of delirium to pyrexia, as shown by the experience of twelve years in University College Hospital, established clearly enough that delirium is not the direct result of pyrexia, as Liebermeister has taught, but had hardly a wide enough basis (199 cases) to solve some of the riddles of the disease. Mr. Savory's recent examination of such specimens of femoral arteries ligatured for popliteal aneurysm as there are in London hospital museums, proved, as far as can be proved from twenty-six specimens, that, as a rule, the femoral artery is not entirely occluded below the point of ligature. Coming now to the class of contributions which may be more or less fairly called clinical summaries, there was a remarkable account by Mr. J. Knowsley Thornton, of 300 cases of complete ovariotomy, and 20 of exploratory abdominal operation. He could show that throughout this long series he had not lost a single case of the removal of a simple cyst or uncomplicated ovariotomy; and the review of the whole proved, as Sir Spencer Wells said, steady progress. The papers by Mr. Barwell, Mr. Jacobson, and Mr. Rivington, on the subject of suprapubic lithotomy, all contributed to the approval of the revival, under certain conditions, both for large and small stones, of that ancient operation of the sixteenth century, or even earlier. Mr. George Pollock touched shortly on the changes in bone and soft tissues after amputation of a limb, which have hardly received as yet the attention from pathologists which they deserve, and which have a very practical bearing on the health and comfort of the stump. Mr. R. J. Godlee and Dr. C. T. Williams approached the large subject of thoracic surgery in discussing the results of bronchiectasis treated by paracentesis in six cases, one of which may be considered to have been cured. The position of a bronchiectasis is hard for the physician to determine accurately, and for the surgeon to approach safely, and it was generally felt that only the slow but sure fatality of bronchiectasis would justify the attempt. A somewhat novel chapter was added to the history of typhoid infection by Dr. J. E. Squire, in an account of his experience of the disease with the troops at Suakim, where there seemed to him good reason to consider that the only possible mode of communication was by the air. The largest group of papers were those which dealt with, or were founded upon, one or two special cases of unusual character. Mr. J. Knowsley Thornton contributed a very remarkable case of excision of a cystic spleen, weighing twenty-six ounces, from a girl, aged 19, who showed no bad symptoms when she was last seen, two years after the operation. Dr. T. Barlow, after a very close observation of a case of a man dying with some paralysis on the eighth day of measles, was able to show some definite lesions of the spinal cord, even in that early stage, which were important as a guide to much of the pathology of nervous sequelæ of acute disease. Dr. Cayley showed a case of large thoracic aneurysm, in which death seemed to have been postponed for about two or three months by the introduction of forty feet of fine steel wire. The discussion which followed showed less disinclination to the trial of this, or similar methods, in very severe cases. Mr. Langton and Mr. Bowlby brought forward a remarkably complete series of specimens from a case of ulcerative endocarditis, to show all the stages between embolism and aneurysm. Mr. Chavasse exhibited a curious specimen of multiple neuromata, in which nearly every spinal nerve (as well as the pneumogastric) was affected with several tumours, but only trifling discomfort was felt; Mr. Jonathan Hutchinson, a case of congenital, and perhaps inherited, alopecia; Mr. J. B. Sutton, one of "harlequin fœtus," or general congenital seborrhœa; and there were many other minor specimens and discussions. It is an excellent habit which this Society alone adopts of publishing not only its papers, but its discussions. The very imperfect summary which our space will permit shows a very full record of industry and learning, and no fear in facing the more difficult of modern problems.

The Clinical Society of London has continued, during 1886, the same career of steady progress in practical medicine and surgery for which it has become noted. As in the previous year, the papers contributed by surgeons have somewhat preponderated, possibly because a surgeon, Mr. T. Bryant, presides over the meetings. It will be convenient to class the papers in two divisions; those contributed by physicians and surgeons respectively. In January, Sir Andrew Clark gave an interesting account of a case which he denominated "desquamative prostatitis," in which there was a discharge of hyaline cylinders resembling renal cylinders. Dr. Angel Money described a new symptom which he had observed in a case of megrim and epilepsy, and which consisted in an apparent momentary lengthening of a written or printed word, seemingly caused by a reduplication of one or more of the letters in the word. Dr. Samuel West related particulars of a case of chronic simple ulcers of the stomach and duodenum, without symptoms until the occurrence of perforation. In February, Dr. W. J. Tyson, of Folkestone, described three cases of universal alopecia, which had recently occurred in his practice. Dr. Hale White read a paper on hysterical pyrexia, which he prefaced by describing the case of a girl whose temperature on two separate occasions when she was admitted into Guy's Hospital rose to 105° Fah. Dr. Goodhart furnished notes of several cases of meningitis which were of obscure origin. The same physician also related particulars of a case in which intussusception of the upper part of the jejunum had existed for twenty-one months, with periodical attacks of pain and vomiting, and progressive wasting, and which, after death, was found to be associated with large polypoid growths in the jejunum. In March, Dr. T. Whipham and Dr. A. T. Myers contributed a paper on some chronic nervous sequelæ of small-pox, especially as affecting the speech. Dr. Samuel West read details of a case of baruria in a woman, with high percentage of urea. In April, Dr. S. Mackenzie read a paper on erythema nodosum, especially dealing with its connection with rheumatism. Dr. Samuel West described three peculiar cases of pneumothorax. Dr. Bristowe read notes of a case of gummata of the liver in a boy, aged 15, treated successfully with iodide of potassium and mercury. Dr. R. W. Burnet described a case of hydatids of the liver, discharged through the right lung, and coughed-up, in which the whole of the lower lobe of the lung was excavated. In May, Dr. Churton, of Leeds, related a case of aneurysm of the thoracic aorta treated by galvano-puncture. Dr. Percy Kidd contributed a case of aneurysm of the aorta, with extravasation of blood into the posterior mediastinum, compressing the œsophagus and vagus nerves, and then rupturing into the abdominal cavity; it was associated, during life, with frequent vomiting. Dr. R. Caton, of Liverpool, reported a case of aneurysm of the hepatic artery, and commented on the extreme rarity of the disease, of which only ten other cases were believed to be on record in European and American medical literature. The aneurysm burst into the hepatic duct. Dr. Hale White described a case of simultaneous inflammation of several serous membranes, namely, the pericardium, peritoneum, and pleura, in a girl aged 19, probably the subject of rheumatism. In October, Dr. Charlewood Turner described a case of congenital malformation of the heart, with systolic and pre-diastolic basic *bruits*. In December, Dr. Herringham read a paper on two cases of diphtheritic paralysis, with heart affections and choreic movements. Dr. Montague Murray related a case of gastric ulcer with unusual complications. The Albumen-Test Committee has presented its report, of which we gave a full account in the JOURNAL for June 26th. The Committee on Myxœdema is still sitting, and it is anticipated that the Committee's report may be presented to the Society during the present session. Large numbers of living specimens have been exhibited at the meetings during the year; but the limited space at our disposal prevents us from enumerating them in detail. The following have been the papers of chief interest to surgeons:—In January, Mr. Clutton read notes of a large cervical spina bifida, which was undergoing spontaneous cure when death supervened from diphtheria. Mr. Sympson, of Lincoln, showed a boy, aged 7, the subject of myositis ossificans, in whom large bony growths occupied the tendons of the latissimi dorsi, trapezii, and other muscles, so that a large saddle of bone was formed in the loin, preventing any bending of the back. Mr. Barker read a paper on a case of ununited fracture of the clavicle, causing pressure on the brachial plexus and writer's cramp, for which excision of the false joint, with wiring of the fragments, was done, perfect union of the bone and complete relief of the nerve symptoms ensuing. Mr. Brudenell Carter described an interesting case of recovery of vision after amaurosis consecutive to malarial fever. In February, Mr. Mansell Moullin read notes of a case of traumatic inguinal aneurysm, with rupture of the sac, treated successfully by ligature of the common femoral and external iliac arteries. Mr. Charters Symonds detailed a case of aneurysm occurring in a stump, resulting from Gritti's amputation, treated also successfully by ligature of the superficial femoral artery, opening of the aneurysm, and ligature of the femoral vessel above and below the sac. Mr. A. E. Barker gave full notes of a case of acute intestinal obstruction in a male, aged twenty-three, followed by acute general peritonitis, and treated successfully by abdominal section, release of the implicated bowel, and thorough sponging out of the peritoneum. The President on that occasion stated that he also considered the existence of acute peritonitis was no bar to the operation of abdominal section. In March, Dr. Roderick Maclaren, of Carlisle, read an account of a case of hernia cerebri suc-

cessfully treated by removing the protrusion and closing the opening in the skull with a silver plate. Mr. Jonathan Hutchinson gave brief notes of a case of necrosis of the lower jaw from the medicinal and long-continued use of phosphorus taken in pills. Mr. Clutton described a case of tubercular ulceration of the palate in a girl, aged 15. Dr. Longhurst gave the particulars of a case of popliteal aneurysm occurring in a patient, the subject of locomotor ataxy, and cured by pressure. Mr. Meredith read notes of a case of successful laparotomy for the relief of acute intestinal obstruction following ovariotomy. In April, Mr. W. J. Walsham described a case of lithotrity at a single sitting in a boy ten years old. Mr. Timothy Holmes related the case of a girl, aged 14, who fell and bruised the right side of the thorax; and in whom, without fracture of a rib, there was subpleural laceration of the lung, from which she recovered. Mr. J. R. Lunn furnished notes of a case of ununited fracture of the patella in a man aged 44, with 4½ inches of separation between the fragments, treated successfully by excision of the knee-joint. In May, Mr. Pick related a case of impaction of stone in one ureter, with atrophy of the kidney on the other side. Mr. R. W. Parker read a paper on the treatment of nævus by excision, and gave a clinical analysis of 564 cases of nævus. Mr. Victor Horsley described a case of suppuration in the mastoid cells, complicated by thrombosis in the lateral sinus, and septic embolism of the heart and left lung, in which recovery followed trephining of the mastoid process, etc.; and supplemented his paper with remarks on the prevention of septic embolism in such cases. In October, Mr. Pearce Gould exhibited a case of undeveloped sexual organs, associated with congenital defect of the tonsils, but believed the impression popularly entertained in this country that the tonsils and testicles are closely connected is erroneous. Mr. F. Treves produced a patient suffering from pulsating tumour of the head, with Raynaud's disease. Mr. Butlin gave further notes of a case of renal lithotomy (published in the *Transactions* of the Society for 1882), showing that the patient had since had stone in the opposite kidney, but had passed satisfactorily through his illness. Mr. Charters Symonds narrated a case of removal of the scapula for osteo-sarcoma, the patient being exhibited at the meeting, and remaining well, two years after the operation. Mr. Thomas Smith described a case of ligature of the common iliac artery with kangaroo tendon, with subsequent yielding of the knot, re-ligature with silk, gangrene of the limb, and death. Mr. Butlin contributed a somewhat similar series of events in a case of axillary aneurysm for which the subclavian artery was ligatured in the third part of its course, with slipping of the ligature shortly after the operation, re-ligature, collapse, and death. These cases gave rise to an animated discussion, in which most of the points relating to the ligature of vessels in their continuity were mooted. In November, one entire evening was taken up by the discussion of excision of the larynx. Mr. Henry Morris described the case of a man whose larynx was excised for epithelioma, and in which death occurred from exhaustion on the eighth day after operation. Dr. Felix Semon narrated a case of successful extirpation of the larynx for epithelioma of the left ventricle of Morgagni. Mr. Butlin related a case of epithelioma of the vocal cord for which partial excision of the larynx was performed, and in which there was, three months subsequently, no sign of return of the disease. Mr. Pick related other cases, and the opinion was expressed that partial excision held out much better hopes of success than total extirpation of the larynx. Another evening was devoted to an interesting discussion introduced by Sir Henry Thompson, who gave a brief sketch of six cases of tumour of the bladder in which he had operated during the last twelve months. He showed the parts removed in each instance, and gave the histories of the cases, and the results. Mr. B. Pitts, described a case of suprapubic lithotomy performed two years after the removal of a growth from the bladder by the perineal operation. Mr. Croft, Mr. Bryant, and Mr. H. Morris also described other cases of tumour of the bladder. Mr. B. Wainwright related a case of vertical fracture of the head of the right radius, and fracture of the coronoid process of the ulna. In December, Mr. Treves read a paper on acute myositis.

The Pathological Society of London.—The most extensive piece of work attempted by the Pathological Society of London during the last year was the collection of a series of cases and papers on tumours of the brain; the fifty-four specimens thus brought together were subsequently classified by a committee appointed for this purpose. In fourteen of the cases the growths were gliomatous, and of these, five were in the cortex; as all the tumours of this class were solitary, the table lends some support to the hope that such tumours may be successfully removed. Moreover, in the sixteen cases in which the growth was sarcomatous, three were in the cortex, one was connected with the envelopes, and four with the nerves, and in only two were multiple growths present. The report of the committee, however, was far from sanguine, as it stated that of the whole series, only two seemed suitable for removal. Several aneurysms of the heart were exhibited by Dr. Frederick Taylor, Dr. Samuel West, Dr. Norman Moore, and Dr. Money. Dr. Pye-Smith contributed an important paper on Teratoma, founded on a remarkable case where the tumour was attached to the liver. Among the dermoid cysts exhibited, mention may be made of an example lying below the tongue, shown by Mr. Stephen Paget, and of a pedunculated dermoid tumour from the sigmoid flexure, shown by Mr. Clutton. Mr. Arbuthnot Lane continued his papers on the osseous changes found in rheumatoid arthritis and in old age, and combatted with much courage certain prevalent opinions as to their causation. Mr. J. B. Sutton, in continuance of his researches in Comparative Pathology, exhibited and discussed a series of specimens of injuries and diseases of joints in animals. Professor Hamilton, of Aberdeen, described his method of making sections of the brain, and exhibited a series of beautiful preparations.

Obstetrical Society of London.—During the past year, many valuable papers have been brought before this Society. In January, Dr. Herman read a contribution "On the Production of the Shape of the Oblique Pelvis of Nægelé." He believed that the dwarfing of one side of the sacrum, rather than ankylosis of the sacro-iliac joint, was the cause of distortion, by leading to altered distribution of the weight of the body. The natural pressure of the femora pushed the acetabula upwards and outwards, as Dr. Champneys had shown; when this pressure was disturbed, so as not to be the same on both sides, the deformity in question developed. The distortion of the pelvis noticed in cases where a patient had had one lower extremity amputated early in life, so that the pressure of the femur on the sound side was unopposed, supported the view that the pressure of the femur was outwards. Nægelé's pelvis was entirely due to altered distribution of body-weight, the bone-structure being sound. Light was not thrown upon the subject by deformities where the pelvic bones themselves had been rendered flexible by disease. Dr. Braithwaite read notes of a singular case of gastrotomy for extra-uterine gestation; the child was successfully removed, but the placenta, which was large, never came away, and was, as he believed, absorbed. In February, Mr. Knowsley Thornton contributed a case in which two dermoid ovarian tumours were successfully removed from a woman in the fourth month of pregnancy. The operation was performed on February 4th, 1885, and the patient was safely delivered of a live child on June 23rd. Mr. Thornton noted that patients operated upon at this period of gestation generally avoided miscarriage, and recovered better than those subjected to operation a month or six weeks later. In March, Dr. Barbour, of Edinburgh, showed a very fine series of frozen sections from subjects who had died in the early part of the first stage of labour, in the third stage, and shortly after the conclusion of parturition. The obstetrical anatomy of the third stage series was shown in specimens from four cases of uteri obtained by Porro's operation. Every medical school in the kingdom should endeavour to add to its museum as many well-prepared specimens illustrating the mechanism of labour and the changes in the uterus as can possibly be obtained. Such specimens will be of far more value to the student than ready-made dissections of the popliteal space and similar preparations, which he should make for himself. Dr. Lewers communicated notes of a case of circumscribed sarcoma of the vagina and uterus. In April, Dr. Matthews Duncan read a valuable monograph "On Contraction, Inhibition, and Expansion of the Uterus." He discussed at length not only the healthy contractions of pregnancy and parturition, but also the contractions said to be present in childhood, and those of menstruation, of dysmenorrhœa, of uteri affected with fibroids, and of abortion. At the next meeting, Dr. Duncan read another communication "On Elasticity, Retraction, and Polarity of the Uterus." This subject, like the former, was discussed in relation to other conditions besides parturition. Dr. Amand Routh read a case of serous perimetritis, which gave rise to a discussion on that remarkable condition. Dr. J. Phillips read in June a monograph on spurious hermaphroditism, based upon four cases which occurred in the same family. In July, some "Observations on the Uterine *Bruit*" were read by Dr. Champneys. This paper contained valuable clinical records of auscultation of pregnant uteri, and of uteri affected with fibroid disease. In October, a very instructive discussion on rupture of the uterus and its management followed the reading of notes of several cases under the care of Drs. J. G. Swayne and Richard Cox. Mr. Alban Doran read a paper on papilloma of the interior of the Fallopian tube, a rare disease, and on the relation of obscure cases of peritoneal effusion to catarrh from the tube. Dr. Champneys, at the November meeting, read a second communication "On the Obstetrics of the Kyphotic Pelvis." He adhered, after further experience, to the con

clusions which he had expressed three years previously in the former paper. The fœtal head was, he maintained, usually more or less transverse at the beginning of labour, and not antero posterior, as usually described during labour. The occiput rarely turned forward; deep transverse position was common, and posterior rotation not uncommon. Lastly, the head sometimes passed out of the pelvis, practically between the tubera ischii in front, and the sacrum and coccyx behind, entirely neglecting the anterior part of the pelvis. The fact that within one year two papers have been read at the same Society on pelvic deformities in woman, suggests that a good concise treatise on the subject would supply a great want. It is highly important that the general practitioner should understand the mechanism of labour as affected by these distortions, but in order to do so, he must understand the meaning of the terms by which they are known, else such expressions as "Nægelé's," "Robert's," "scoliotic," "kyphotic," "spondylolisthetic," and "spondylolisthematic" pelves only serve to keep him from reading valuable papers which bear any of these terms for their title. Dr. Walter Griffith's *Scheme*, published in the nineteenth volume of the *St. Bartholomew's Hospital Reports*, would form an excellent basis for classification in such a work. At the December meeting, Dr. Dakin read a paper on mercurial poisoning in lying-in women, through solutions of corrosive sublimate employed for the douche. The cases of poisoning occurred together at a particular date. The great benefits which had followed the substitution of corrosive sublimate for Condy's fluid and carbolic acid, as proved by the statistics of the General Lying-in Hospital, more than counterbalanced the occasional appearance and symptoms of mercurialisation. A large number of pathological specimens were exhibited at the meetings, many being of high scientific interest.

The British Gynæcological Society.—During the past year Mr. Bland Sutton and Dr. Johnstone each read papers on the condition of the mucous membrane of the uterus during menstruation. Though working from different starting points, they both arrived at the same conclusion, namely, that it is only the epithelial layer which is shed or disintegrated. Dr. Grigg contributed a valuable paper on puerperal eclampsia. Dr. Bedford Fenwick has done good work in pointing out the relation between intra-abdominal tumours and cardiac degeneration. He related eighteen cases in which this condition was discovered *post mortem*, where death had resulted from some form of abdominal tumour. A long and exhaustive paper was contributed by Dr. Barnes on vicarious menstruation. The conclusions arrived at were that vicarious, or supplementary functional action, was a fundamental law in physiology; that there was nothing exceptional in vicarious menstruation; that vicarious menstruation might occur under various phases; and that it was conservative in intent and action, lessening or averting evil. In the discussion on the paper, Dr. Wilks expressed his scepticism as to the existence of vicarious menstruation. A unique case of pyometra was recorded by Dr. Fancourt Barnes. Over eighteen ounces of pus were released from the enlarged uterine cavity by dissecting up an occluded vagina in a multipara. Among other papers of interest was one on serous peritonitis by Dr. Edis.

The Medical Society of London, with its weekly meetings, has maintained the interest which attaches to the transactions of this venerable Society. The Lettsomian Lectures, delivered on January 4th and 18th and February 1st, by Mr. Jonathan Hutchinson, on "Some Moot Points in the Natural History of Syphilis," were of more than usual interest, treating, as they did, of sundry ill-understood phenomena in connection with that disease. The suggestions thrown out, though by no means universally accepted, were marked by the close observation and clinical insight characteristic of the author. The subject of the treatment of varicocele by excision, brought forward by Mr. A. Boyce Barrow, gave rise to an animated discussion on January 11th, as to both the method and the propriety of surgical intervention. On March 15, Mr. Edmund Owen showed a very successful case of excision of the upper end of the femur by Jordan's method, in which the portion removed had been reproduced, with the best results. On March 1, Dr. Hughes Bennett read a somewhat remarkable paper on "Spastic Paralysis:" a morbid state, as he observed, of widespread occurrence and great importance. He dealt with the subject exhaustively, both from a clinical and a pathological point of view. The papers of Dr. Day, on "Irritable Brain," on March 29, and of Dr. John Lowe, on "Traumatic Hydronephrosis," on April 5, were both possessed of interest. On April 12, Mr. R. Brudenell Carter exhibited a boy, nine years of age, on whom he had successfully performed Dr. Mules's operation of evisceration of the eye, followed by the insertion of a ball of glass, to preserve the size, contour, and movements of the globe; and on the same evening Dr. Sa West read some instructive notes on the family history of a case of hereditary tremors. Since the opening of the present session, Mr. Lawson Tait read a paper, before an unusually large audience, on the "Principles involved in the removal of the Uterine Appendages." In this paper Mr. Tait vigorously defended the practice which he has done so much to make popular. He impugned the arguments, the statistics, and the inferences of his opponents, and, on the ground that nothing succeeds like success, he claimed the sympathy and support of the profession. He dealt fully with the cases in which the operation was desirable, but was less explicit regarding those in which it should *not* be performed. The discussion which followed was perhaps less animated than had been anticipated, and no serious attack was made on Mr. Tait's position or practice. On a subsequent evening, Dr. Lewers contributed a valuable essay on the "Etiology and Pathology of Rupture of the Uterus during Pregnancy;" and on November 15, Dr. Hughlings Jackson read a paper on "A Rare Case of Epilepsy." Mr. Victor Horsley afterwards made some remarks on the subject, illustrated by limelight projections of a series of photographs of guinea-pigs, in which a similar condition had been artificially induced. The problem of cerebral localisation is evidently progressing in the hands of Mr. Horsley and his fellow-workers.

Ophthalmological Society of the United Kingdom.—The work done during this year by this Society has, if we mistake not, fully maintained the reputation and position of the Society. First and foremost, we may mention the discussion on Graves' disease, which took place in the spring. The Council issued a series of questions, to which they invited answers; the questions related chiefly to cases completed either by death or recovery, to the effects of treatment, to the etiology of the affection, and to certain points especially belonging to the eye; for example, Graefe's lid-sign, etc. Amongst those who took part in the debate, we may mention Mr. Jonathan Hutchinson, Dr. Bristowe, Dr. Wilks, and Dr. Hughlings Jackson, who, with a host of lesser celebrities, made communications of facts, many of which have added to or consolidated our knowledge of this strange malady in important respects. During the summer the long-expected report of the Special Committee on Sympathetic Ophthalmia was presented by Mr. Nettleship, the two years or more occupied in its production being fully explained when it was found to be based on the analysis of more than two hundred cases. Of the individual papers, it is not too much to say that several were of first-rate excellence, and dealt with the subjects concerned in an exhaustive manner. Without placing them in any special order, we would mention those of Mr. Priestley Smith on Primary Glaucoma in relation to Age, Mr. Nettleship on Meningitis after Excision of the Eyeball, Mr. Jessop on the Affections of the Eye in Herpes Facialis, Dr. Sidney Coupland on Thrombosis of the Cavernous Sinus, and the quite recent communication of Mr. Edgar Browne on Quinine Amaurosis. Mr. Lawford read an interesting paper on Tubercle of the Choroid, with especial reference to the tubercle bacillus; and Mr. Carter read a paper on Cataract Extraction. Many minor communications were made, of varying degrees of interest; we can only mention here that of Mr. Edgar Browne relative to the painting of a colour-blind artist. In conclusion, we must not forget the second Bowman Lecture, which was delivered by Professor von Zehender, of Rostock, and which appeared so lately in our pages that further reference to it is unnecessary.

The Society of Medical Officers of Health has endeavoured to make its proceedings more attractive to that large body of health officers whose duties are not confined to metropolitan administration. By the appointment of Professor Corfield, and of his successor Dr. Alfred Hill, as Presidents, assurance was given that the work of the Society would embrace subjects associated with sanitary administration in all parts of the country. A large accession of members has been the result. A number of valuable papers have been contributed, which have since appeared in an excellent volume of *Transactions*. Among the chief of these was a communication by Dr. Heron on the cholera-bacillus of Koch, in which the author offered strong arguments in favour of Koch's teachings. A further paper by Professor Bischof showed that at present too much reliance must not be placed upon the gelatine-peptone water test. Mr. Eassie, in a paper "On the Waters derived from the Bagshot Beds considered as Drinking Supplies," gave the result of original investigations of much value into the opportunities of pollution of waters from these sources. The presidential addresses by Dr. Corfield on the History of House Sanitation, and by Dr. Hill on Methods of Refuse Disposal, dealt thoroughly with these subjects, and form a useful contribution to our knowledge of them.

The Epidemiological Society.—The Epidemiological Society had under consideration a series of interesting papers from well-known epidemiologists. The presidential address by Dr. Walter Dickson gave an account of some recent epidemics at home and abroad. A com-

munication from Dr. Cameron, of Hendon, excited much attention, his subject being the cow disease, which had been associated by Mr. Power with a serious outbreak of scarlet fever among the drinkers of milk coming from the farm on which the cow-malady prevailed. The chronicity of diphtheria, or rather its recrudescence in some individuals, was discussed by Dr. D. Astley Gresswell, who showed much reason for thinking that these persons might in this way retain a power of infection. A further meeting was devoted to the discussion on an excellent paper by Dr. E. J. Edwardes on the Recent German Vaccination Commission. Other evenings were occupied by papers by Dr. Buchanan on Certain Alleged Injuries from Vaccination near Stettin, by Dr. Thorne Thorne on the Recent Sanitary Conference at Rome, and by Dr. G. B. Longstaff on the Statistics of Hydrophobia, Sir William Smart giving an account of the behaviour of cholera in ships. The volume of *Transactions* may shortly be expected.

Academy of Medicine in Ireland.—We have to record with pleasure the continued and increasing success of the Academy of Medicine in Ireland, which, in 1886, passed through the fourth year of its existence. The Fellows, Members, and Student Associates numbered, at the beginning of the Session, 211, 35, and 24 respectively; compared with 208, 27, and 24 in the preceding year. Besides this, the bead-roll of Honorary Fellows now includes the following distinguished names:—Professor Billroth, of Vienna; Professor Charcot, of Paris; Professor Emmet, of New York; Mr. Jonathan Hutchinson, F.R.S., of London; Sir William Jenner, Bart., F.R.S., of London; Dr. Thomas Keith, of Edinburgh; Professor Kölliker, of Würzburg; Sir Joseph Lister, Bart., F.R.S., of London; Professor Ludwig, of Leipsic; Sir James Paget, Bart., F.R.S., of London; Professor Pasteur, of Paris; Professor Schroeder, of Berlin; Mr. John Simon, F.R.S., of London; Professor Virchow, of Berlin; and Professor von Recklinghausen, of Strassburg. One Honorary Fellow died during the year—namely, Dr. Austin Flint, of New York. The meetings of the various sections and sub-sections took place regularly throughout the Session, and in some instances it was found necessary to hold special meetings in order to continue and conclude discussions on subjects of importance. In this connection we cannot hope to do more than mention the titles of the principal communications made to the Academy, with the authors' names. In the Medical Section, the communications were:—A case of true relapse in enteric fever, by Dr. J. W. Moore; partial embolism of the inferior division of the central artery of the retina, associated with repeated previous attacks of chorea, by Mr. Arthur H. Benson; on the therapeutic uses of the digestive ferments, by Dr. J. M. Purser; on some cases of pneumonia, by Mr. James Martin, of Portlaw; hyperpyrexia in rheumatic fever, by Mr. W. Langford Symes; periostitis following enteric fever, by Dr. H. C. Tweedy; the cardiac murmurs of the mitral area, by Dr. C. J. Nixon; a case of enteric fever, fatal by perforation, by Dr. Wallace Beatty; on the quantitative estimation of albumen, urea, and sugar in urine, by Dr. F. R. Cruise; clinical notes on a case of lichen planus, by Dr. J. Magee Finny; a case of enteric fever with unsual symptoms and morbid appearances, by Dr. James Little; a case of cerebro-spinal meningitis, by Dr. Richard A. Hayes; and cancer of the bronchial glands and lung, by Mr. M. A. Boyd. Before the Surgical Section papers were read by Mr. Kendal Franks on the advantages of the principle of dry dressings in antiseptic surgery and on the nature of scrofulous glands in the neck and their surgical treatment; Mr. R. F. Tobin, on the surgery of the late expedition to Suakim; by Dr. William McKeown, of Belfast, on a method of making an artificial opening in the membrana tympani, and of keeping it open for a considerable period, and on its therapeutic influence; by Mr. W. I. Wheeler, on pharyngocele and dilation of the pharynx, with existing diverticulum of the lower portion of the pharynx lying posterior to the œsophagus, cured by pharyngotomy, being the first case of the kind recorded; by Dr. E. H. Bennett, on extroversion of the urinary bladder, treated by Wood's operation; by Mr. W. Thornley Stoker, on bone-drainage in hip-joint disease; by Sir William Stokes, on bone-drainage in the treatment of the early stages of hip-joint disease; by Dr. Henry Fitzgibbon, on a case of ununited fracture of the humerus, and a method of treatment thereof by means of metal screw-taps, and by Mr. P. J. Hayes on electrolysis for the treatment of urethral stricture. In the Obstetrical Section, the chief contributors of papers were Dr. Lombe Atthill, on ovariotomy; Dr. T. More Madden, on displacement of the ovaries, on the treatment of chronic cystitis in women, and on the so-called laparotomy epidemic; Dr. W. C. Neville, on axis-traction in instrumental delivery, with a description of a new and simple axis-traction forceps, and on the treatment of presentations and prolapses of the funis; Dr. W. J. Smyly, on two cases of fibro-myomatous tumour of the uterus, and on the use of the curette in the diagnosis and treatment of disease of the uterine mucous membrane; and Professor Dill, of Belfast, on labial hæmatoma or puerperal thrombus. To the Pathological Section the communications were very numerous. The principal were—pathology of lead paralysis, by Dr. Wallace Beatty, who also showed and described the lungs from a case of pyo-pneumothorax; a milky fluid from a case of ascites, by Dr. G. F. Duffey; tumour of inferior saphena vein, by Mr. J. K. Barton; specimens from a case of Bright's disease, by Dr. A. W. Foot, who also exhibited a case of spontaneous rupture of the heart; osteomalacia, by Dr. E. H. Bennett, who at another meeting demonstrated certain laryngeal changes subsequent to laryngo-tracheotomy; a case of dentigerous cyst, by Mr. A. W. W. Baker; ulcer of the stomach, opening into the left ventricle of the heart, by Dr. J. Magee Finny, who also showed a case of pericarditis; a case of villous disease of the kidney, followed by hypertrophy, degeneration, and rupture of the heart, by Mr. W. Thornley Stoker; cancer of the liver, by Dr. James Little; mitral and aortic disease, by Dr. Walter G. Smith, who likewise presented an interesting specimen of ulcerative endocarditis, limited to the right side of the heart; a case of malignant endocarditis, by Dr. J. M. Purser; endocarditis, with localised pericarditis, by Dr. C. J. Nixon; rupture of a pelvic cyst, by Dr. Charles B. Ball; red granular kidney, by Mr. M. A. Boyd; and zonular cataract and dental malformations, by Mr. John B. Story. Nor were the sub-sections idle. To the sub-section of State Medicine communications were made by Mr. D. Edgar Flinn, on the duties of medical officers of health in England and Ireland contrasted; by Dr. C. F. Moore, on some considerations in reference to the sanitary condition of the Dublin dairy yards; by Dr. A. H. Jacob, the working of the Contagious Diseases Acts; by Dr. H. Colpoys Tweedy, cremation, its sanitary and judicial aspects; and by Dr J. W. Moore, remarks on the climate of Dublin, based upon twenty years' observations. Lastly, the sub-section of Anatomy and Physiology received elaborate communications from Dr. H. St. John Brooks, on variations in the nerve supply of the flexor brevis pollicis muscle, and on the morphology of the intrinsic muscles of the little finger, with some observations on the ulnar head of the short flexor of the thumb; from Dr. F. T. Heuston, on complicated muscular anomaly in the human arm; and from Dr. F. A. G. Davis, on irregularities of the thoracic duct. Some important official changes took place at the beginning of the session. Dr. Banks, the first President of the Academy, vacated his office on the completion of the third year of his presidency, and was succeeded by Dr. Robert McDonnell, F.R.S. Dr. George F. Duffey was elected General Treasurer, in room of Dr. McDonnell; Mr. William Thomson was re-elected General Secretary; and Dr. J. W. Moore was re-appointed Secretary for Foreign Correspondence.

In addition to those of the Societies above mentioned, condensed reports of the proceedings of the following Societies have appeared during the year: The Harveian Society, the West London Medico-Chirurgical Society, the Leeds and West Riding Medico-Chirurgical Society, the Cambridge Medical Society, the Sheffield Medico-Chirurgical Society, the Manchester Medical Society, the Manchester Pathological Society, the Glasgow Pathological and Clinical Society, the Glasgow Obstetrical and Gynæcological Society, the Wolverhampton and District Medical Society, the Brighton and Sussex Medico-Chirurgical Society, the Midland Medical Society, the Chester Medical Society, the Sunderland and North Durham Medical Society, the Northumberland and Durham Medical Society, the West Kent Medico-Chirurgical Society, the Plymouth and Devonport Medical Society, the Harrogate Medical Society, the Liverpool Medical Institution, the Yorkshire Association of Medical Officers of Health, and the Odontological Society of Great Britain.

ANATOMY.

Skull. Brain and Nervous System.—Alimentary Canal and Peritoneum. Orbit.—Vertebral Column.—Migration of Testis.—Pineal and Pituitary Bodies.—Embryology.—Abnormalities.

DURING the year which has come to a close, anatomy has made solid progress. Without doubt very little can be added to the mere details of human anatomy; but much remains to be done in the way of rational explanation and elucidation. The materials which are available for this purpose are of inexhaustible extent, and even the labours we have to chronicle have made but a slight impression upon them.

The Skull.—The structure and development of the skull is a subject which Mr. W. Kitchen Parker has made especially his own, and during the year this most painstaking and laborious worker has made an important addition to our knowledge by the publication in the *Transactions of the Royal Society* of two additional monographs upon

the subject; one upon the skull of the edentata, and the other upon the skull of the insectivora. Another important contribution to our knowledge of the skull is contained in an exhaustive monograph written by Herman Welcker (*Archiv. für Anthropologie*, 1886. Die Capacitat, &c., der Schadel Kapsel bei den verschiedenen nationen), and although of very much smaller scope than the monographs which have been mentioned, we may refer to the series of monographs which are being published by Professor Macalister upon the cranial bones in the *Transactions of the Royal Irish Academy*. These cannot but prove of service, and it is to be regretted that they are so little available to the ordinary student.

The Brain and Nervous System.—Professor Hamilton has continued his researches upon the Corpus Callosum. His paper is entitled, "Is the Commisural Theory of the Corpus Callosum Correct?" (*Rep. Brit. Assoc.* 1885-86), and we would refer our readers to the paper for an answer to this very pertinent question. A very good account of the corpus callosum in fish, amphibians, and reptiles is also contained in a paper by an American anatomist, Dr. H. F. Osborn (*Morph. Jahrbuch*, 1886, p. 223). Moreover, in our own columns we have published Dr. Alexander Hill's college lectures on questions connected with the brain ("The Brain Mechanism of Sight and Smell," BRITISH MEDICAL JOURNAL, March 6, 1886), in which the author ingeniously argues various abstruse points, and points out an interesting similarity in the minute structure of the sense organs—the eye, ear, and nose. The peripheral part of the nervous system has been very carefully considered by Dr. Herringham, in a paper upon the "Brachial Plexus," read before the Royal Society. ("The Minute Anatomy of the Brachial Plexus," W. P. Herringham, *Proc. Royal Soc.*, No. 243, 1886.) The author can claim to have placed a difficult subject upon a more rational basis.

The Alimentary Canal and Peritoneum.—The alimentary canal and peritoneum have been most laboriously examined by Mr. F. Treves, who has systematically dissected and described the appearances found in two hundred mammalia. The abstract of Mr. Treves's lectures upon this subject were published in our columns (BRITISH MEDICAL JOURNAL, March 27th, 1886, p. 582, *et seq.*), but doubtless such valuable material will be treated at greater length in another form. We may refer to a paper bearing upon the same subject by Pilliet and Boulart ("Sur l'estomac de l'hippotame, du kangaroo," etc., *Journal de l'Anatomie et de la Phys.*, p. 402, 1886).

The Orbit.—Besides the lectures which have been mentioned, our columns have contained abstracts of Dr. Brailey's lectures upon the muscles, ligaments, fasciæ, etc., of the orbit. Coming soon after Mr. Lockwood's able paper on the same subject, it will be interesting to see whether Dr. Brailey can confirm Mr. Lockwood's important and new observations, and we await with interest the publication of the lectures in full.

Vertebral Column.—The axial skeleton has also received its share of attention at the hands of Professors Cunningham and Sir William Turner. The former (*Journal Anat. and Phys.*, p. 238, 1886) discusses the vexed question of "The Connection of the os odontoideum with the body of the axis vertebra," and the latter in the same journal (p. 322) gives interesting statistics concerning "The Sacral Index in various Races of Mankind." Moreover, the last-mentioned anatomist has adduced evidence to show that even the things we think least variable may undergo modification, and in a paper on "The Lumbar Curve of the Spinal Column in several Races of Man" (*Journal Anat. and Phys.*, p. 536, 1886) he argues that the Chinese and Europeans have convex lumbar regions, the Andamanese, Negros, Maoris, Sikhs, and perhaps Hindoos, Esquimaux, and Lapps have straight lumbar regions; whilst the Australians, Bush, and Sandwich Islanders would have concave lumbar regions.

Migration of Testis.—Hardly a year passes without some observer essaying to explain that curious phenomenon—the transition of the testis, and Messrs. Debierre and Pravasz may claim that their paper on the subject ("Contribution à l'étude du Muscle crémaster du Gubernaculum testis et de la migration testiculaire," *Lyon Médicale*, 1886, Nos. 21, 22 and 23.), places it upon a better footing. They recognise that the internal cremaster is an upward prolongation of the gubernaculum, but in this observation they have been forestalled by Mr. Lockwood, who also treats of this subject in his paper on Infantile and Encysted Hernia (*Transactions of the Royal Medical and Chirurgical Society*, vol. lxix.). Moreover, the last-named author attributes an important pathological function to these fibres, and considers them competent to cause a migration of the cæcum or the production of the sac of an infantile hernia. Also in connection with the anatomy of the genito-urinary tract we may notice Mr. Bland Sutton's careful paper on "The Origin of Certain Cysts" (*Journal of Anat. and Phys.*, 1886, p. 432), in which he makes interesting observations upon the relation of the mesonephron to the ovary; and also upon the ultimate fate of the Wolffian duct in the female.

Pineal and Pituitary Bodies.—Not long ago the anatomical world was interested by the announcement that the pineal body was a rudiment of a long-lost eye, and recently Mr. W. Baldwin Spencer has published his monograph on "The Presence and Structure of the Pineal Eye in Lacertilia" (*Quarterly Journal of Microscopical Science*, October, 1886, p. 165). The writer attributes to de Graaf the merit of having clearly shown that in one particular animal the pineal gland actually is modified into a structure comparable to an invertebrate eye. Mr. Spencer, however, carries the observations much further, and shows that in many lizards this invertebrate eye possesses a cornea, lens, and retina of unanticipated perfection. The paper is one with which every anatomist should hasten to make himself acquainted. Whilst the epiphysis cerebri has been so well observed, the hypophysis has not been neglected. An exhaustive paper in the *Archiv für Micros. Anatomie*, 1886, p. 257, "Untersuchungen an der Hypophyse einiger Säugethiere und der Menschen," deals with its histology in the horse, cat, dog, rabbit, pig, and man.

Comparative Embryology.—Our space does not permit us to mention a tithe of what has been done in the field of comparative embryology, but perhaps we may notice Flemming's attempt to show that in the rabbit the Wolffian duct originates from epiblast ("Die Ektoblastische Anlage des Urogenital Systems beim Kaninchen," *Arch. für Anatomie und Phys.*, 1886, p. 236). Such an observation as this would, if clearly proved, reconcile many discrepancies; but it is so out of accord with what occurs in other vertebrates that, without doubt, even after Speer's paper showing a like origin in the dolphin, more evidence will be demanded upon this point before its acceptance. We may also refer to a useful paper by Heufe upon the development of the mole (*Quarterly Journal of Microscopical Science*, vol. xxvii, pt. 2, p. 140). We have already noticed in our columns the third instalment of His's great work upon Human Development; and, although it appeared towards the end of 1885, its importance is so great that it will not be out of place to mention it again (*Anatomie Menschliche Embryonen*, pt. iii; *Zur Geschichte der Organe*, Leipzig, 1885).

Abnormalities.—As usual, the various abnormalities met with have been recorded, and Wenzel Greuber (*Beobachtungen aus der Menschlichen und Vergleichenden Anatomie*, Berlin, 1886) continues his exhaustive records of anomalies. Moreover, the Guy's demonstrators have given a brief record of various rare deviations met with in the dissecting room of that institution. ("Abnormalities Observed in the Dissecting Room of Guy's Hospital during 1880 and 1884." Hale White, Arbuthnot Lane, and J. A. P. Price. *Guy's Hospital Reports*, 1886.) Although the labours which we have briefly mentioned are but a portion of what has been achieved during the anatomical year, they show, nevertheless, that steady and continuous progress is being made in this important branch of knowledge, and it may be claimed that the year compares favourably with any that has gone before.

PHYSIOLOGY.

Histology.—Protoplasm, Nerve and Muscle.—Special Senses.—Brain.—Spinal Cord and Reflexes.—Peripheral Nerves: Visceral Nerves.—Digestion and Nutrition.—Glandular System.

DURING the past year, numerous papers have been published on physiological subjects; those which are most important, and have a practical bearing on medical science, will be noticed here:—

Histology.—Of the researches on histological subjects published during the last year, many dealt almost exclusively with comparative histology; and though this direction of research is likely to consolidate and increase our knowledge concerning the tissue-elements of human structures, space does not allow of any discussion here of the results obtained. Flemming has described the formation of karyokinetic figures in the ovaries of mammals during the loss of the Graafian follicles. In thin sections of ovary, hardened in a mixture of chromic, osmic and acetic acids, and stained with sapranin or gentianin, the chromatin of the nucleus was found in the form of irregular or round bodies, while the nucleus itself was more or less disintegrated. There was altered chromatin in the liquor folliculi. Osmic acid preparations showed fatty degeneration of the cell substance. Flemming explains these signs by a disappearance of the follicle through so-called atresia, and designates the process as chromatolysis. He did not notice any wandering of leucocytes through the follicular sheath, as has been stated by some authors. The degenerated follicles showed many karyo-kinetic figures, while none were found in normal ripe follicles. Ehrlich has made some interesting observations as to the action of methylene-blue, which may possibly have an im-

portant bearing on future experimental researches on the nervous system. He has found that, when methylene-blue is injected into the circulation of the living rabbit, it stains all sensory fibres, the nerve-endings of taste and smell and the nerves of involuntary muscle and of the heart, while the motor nerve-endings of voluntary muscle, with few exceptions, are uncoloured. In the central nervous system were stained relatively large bundles, especially abundant in all the nerve-nuclei of the medulla oblongata, much fewer in number in the cerebrum; and a thick band of the finest varicose nerve-fibrillæ attached to the ganglion-cells (cortex cerebri). The colouring, Ehrlich thinks, is probably due to the sulphur contained in the methylene-blue, since dimethyl-phenyl-green, which differs from it only in not containing sulphur, has not the staining re-action of methylene-blue. He thinks, moreover, that only those nerve-endings which are saturated with oxygen become coloured, and that these must have an alkaline reaction. If these conclusions are confirmed by subsequent researches, much light will be thrown on the intimate changes occurring in nervous elements. De Graaf has made an extremely interesting research into the development of the pineal gland in amphibians and reptiles. He finds degrees of development in various genera, which taken as a series, show that the pineal gland is the remains of a once functional eye. Thus, during development, a portion of the gland is constricted off, and appears through an opening in the parietal bones, as what de Graaf calls the "corpus epitheliale." This body is united with its place of origin by a connective-tissue pedicle, which in an early stage contained a bundle of nerve fibres. The clue to the morphology of the pineal gland is found in the blind worm, in which the corpus epitheliale has a structure resembling the eye of one of the higher invertebrate animals, for example, a cephalopod: since its sheath contains long cylindrical cells like retinal rods, and pigment granules, while there is an embryonic lens and a vitreous space filled with protoplasmic tissue. These results are of interest in connection with the discovery by Baldwin Spencer (of Oxford) of a third, median, eye in some lizards, such as hatteria punctata (one of the lowest of the lizard tribe), the iguana, the chameleon, and lacerta ocellata. Moreover, in some extinct animals, the labyrinthodonts of the carboniferous period and fossil saurians, there is a parietal foramen, which would suggest the place of exit of a nerve going to a median eye, such as exists in the living hatteria.

Protoplasm, Nerve and Muscle.—Hermann has shown that during the passage of a galvanic current through water in which small animals (tadpoles, etc.) are swimming, they all become quiet, with their cephalic extremity towards the positive pole: at the opening and closing of the current they become restless. Romanes has tested the action of high pressure on the excitability of muscular tissue and of the heart: up to 150 atmospheres he found no effect produced, the heart of the frog going on pulsating and the muscle contracting to as small a stimulus as before subjection to high pressure. At a still higher pressure, another observer found that the irritability of muscular tissue was not altered, though the protoplasm ultimately died from the absorption of water.

Photography has found an interesting application in the registering of rapid movements of parts of the body, such as those of the pupil and of the vocal cords; it has also been applied to the determination of the velocity of the blood. The experiments were made in Tarchanow's laboratory in Kasan.

Special Senses.—Goldscheider has continued his researches into the distribution of sensory areas in the skin, and has during the year published the results as regards warm and cold sensory nerves. He finds that there are definite points in the skin, by stimulation of which the sensation of cold or warm may be produced. The sensation obtained by stimulating a "cold-point" is momentary and sharp; when a "warm-point" is excited, the sensation is accrescent and more diffuse. It is interesting to find that the temperature-points of sensation give no sensation of pain by mechanical or thermal stimulation. Temperature-points range themselves in chains and lines to one another, radiating from definite points, which might be called "radiating-points" or "centres of temperature-points." The chains of the cold-points are not the same as those of the warm-points, though the radiating-points are the same. For the localisation of these points, and for the numerous interesting experiments performed by the author, the original must be consulted.

Gradenigo, jun., has made some interesting experiments on the retina. He confirms the observations of Engelmann and of Angelucci, that the action of light on the cones and rods of the frog's retina is to cause the inner limbs of the former and the outer limbs of the latter to become shorter and thicker; and states that warmth produces exactly similar changes. The retinæ were fixed with nitric acid (3½ per cent.) and stained with logwood, and then examined microscopically as to the size of the rods and cones. Before the shortening of these elements, the pigment-granules began to spread between the rods; and the order of change afterwards was: shortening of the cones and outer limbs of the rods, then of the inner limbs; and, lastly, the nuclei became longer and more oval. For testing the action of warmth, the eye of a frog was excised under red light, and then was exposed to a temperature of 30° to 36° C.

Adduco and Mosso have made some experiments on the sense of taste, which are interesting from a physiological point of view. They found that ice diminished the sense to all kinds of taste—bitter, sweet, acid, and salt. Cucaine, however, removed only the taste for bitters, and that rapidly; while caffeine and morphine removed this taste more slowly, acting by exhaustion and not by paralysis, as cucaine does. It was found also that a 2 per cent. solution of sulphuric acid for 15 to 20 minutes, followed by distilled water, caused a sweet taste; and that quinine caused a sweet taste at the tip, and a bitter one at the back of the tongue.

In a case where, by the spread of disease from purulent inflammation of the middle ear, the upper part of the cochlea (one-and-a-half turn) was destroyed, Stepanow found that the perception of low tones was not lost; in fact, no tone-defect could be ascertained by examination, nor was there any loss of appreciation of whispering.

Brain.—Last year Ott and Richet had, independently, published experiments relating to the existence of a heat-centre in the brain, by irritation of which a rise of body-temperature was produced. Aronsohn and Sachs have made further experiments, with the result of more exactly localising the excitable region. These experiments were performed on rabbits, dogs, and guinea-pigs, and consisted in puncturing the brain, with antiseptic precautions, through a trephine opening in the angle between the coronal and frontal sutures, one millimètre from the longitudinal sinus. The needle, passing perpendicularly to the surface, traversed the cortex, the white substance of the fore-brain, the middle of the side of the caput corporis striati (near the nodus cursorius of Nothnagel), and the basal medullary layer and cortex. The puncture is effective only if it pierces the region of the corpus striatum mentioned, and the basal medullary layer and cortex. Puncture of parts in front and behind this region are without result. If the basal medullary layer and cortex be pierced, the maximum temperature is reached in two to seven hours; if the region of the caput corporis striati, the temperature rises more gradually, and does not reach its maximum before twenty-four, thirty, fifty, or even seventy hours. The rise of temperature is always febrile, and is accompanied by increase of respiratory movements and of frequency of the pulse. Some days after the injury, temperature, respiration, and pulse become normal, but a fresh puncture will cause the same phenomena to appear as at first. These results are extremely important in regard to the pathology of fever, and show, as the authors state, that a high temperature can be "purely nervous," without the agency of any modified waste-product of metabolism, or that of parasitic organisms being added.

Bechterew and Misslawsky have investigated the influence of the cortex of the cerebrum on the blood-pressure, and the activity of the heart; and Stricker has worked at the same subject. The former observers found that in a curarised dog there was a rise of blood pressure on stimulating, with a weak faradic current, all the part of the sigmoid gyrus lying behind the cruciate sulcus, the portions of the first and second primary convolutions touching this part of the gyrus, and the median part of the anterior division of the sigmoid gyrus, while a fall of blood-pressure followed stimulation of portions of the second and third primary convolutions, and of the part of the fourth adjoining the Sylvian fossa. The rise or fall of blood-pressure is preceded by a latent period. By excitation of the motor region, quickening of the pulse was observed. Stricker found a rise of blood-pressure on stimulating the cortical motor region, with or without a latent period of some seconds, and preceded by a fall when there was a latent period; a similar result was obtained by exciting the front portion of the corpus striatum, while excitation of the optic thalamus was without result. The rise of pressure was unaccompanied by a slowing of the pulse. Marchi has experimented on the results of extirpation of the cerebellum in dogs and monkeys, and has found that total extirpation caused diffuse sclerosis, especially of the grey substance of the pons Varolii lying round the pyramids, and that of the lower olivary bodies; of the peduncles of the cerebellum, and implicating Flechsig's direct cerebellar tract. The extirpation of one lateral lobe caused the same parts to be degenerated, but chiefly on the same side as the lesion: it was found, also, that the degenerated fibres of the superior cerebellar peduncle do not completely decussate with those of the opposite side. Extirpation of the middle lobe caused bilateral degeneration of definite bundles. Though no affection of nerve-nuclei could be

found, yet there was degeneration of the nerve-fibres in several cranial nerves, and in the anterior roots of the spinal nerves.

Spinal Cord and Reflexes.—Wassilieff has shown that the application of a gentle stimulation to the dorsum of the tongue causes it to assume a spoon-shape, from the middle to the root. Stimulation of the hard palate also causes the reflex action, which is supposed to be useful in the formation of the bolus. The faradic current is active in eliciting this reflex, whilst the constant current and thermal and chemical stimuli are inactive. De Watteville has shown that in healthy persons there is a "jaw-reflex," of similar character to that described by Beevor in certain forms of nervous disease.

Schiff had stated that, about four days after division of the posterior columns in dogs, excitation of the cortical motor region produced no muscular contraction, and explained the result by supposing an ascending degeneration to the cortical centres. Horsley, however, has repeated the experiments, and finds that, some days after division of the posterior columns in dogs, excitation of the cortex does produce movements; and, from microscopical examination, it was seen that the degeneration in the cord was only local, spreading one or two millimètres on each side of the point of section. In some cases there was very slight degeneration, so that no tactile anæsthesia was produced.

Experiments showing the influence of the cortex of the brain on blood-pressure in the dog have already been mentioned. Smirnow has investigated the vaso-motor centres in the spinal cord, continuing a line of research which has been diligently followed by many observers of late years. He confirms Laffont in stating that, in the rabbit, vaso-dilator nerves leave the cord between the first and third dorsal vertebræ; so that, if these nerves be divided, no dilatation of vessels ensues on stimulating the depressor nerve. By tying all the arteries going to the brain in the dog, and dividing the spinal cord at certain levels, the influence of the medullary vaso-motor centre could be removed. It was found that, when the section of the cord was made at the level of the third dorsal vertebra, stimulation of the brachial nerve caused a fall of blood-pressure, with slowing of the pulse, uninfluenced by section of the vagi or Ansæ Vieussenii. After section above the first dorsal, there was no fall of pressure on stimulating the brachial nerve; and after section below the sixth dorsal vertebra, there was but slight fall in the same stimulation, and no rise at all on stimulating the sciatic nerve. The results show that from the cord at the level of the first three dorsal vertebræ vaso-dilator nerves take their exit; and at the level of the third vertebra, vaso-constrictor fibres. The author considers the cord as a system of centres of vaso-dilator and vaso-constrictor nerves, arranged in a series.

Kowalewsky has performed some extremely interesting experiments on the nervous mechanism connected with dilatation of the pupil. His conclusions are, that there is an automatic intracranial centre for dilatation of the pupil (in cats), from which bundles of nerve-fibres pass down each lateral column of the cervical cord, and then through the cervical sympathetic to each eye; so that each eye receives fibres from both lateral columns. There is a similar intracranial centre and channel in the cord for the movements of the nictitating membrane, for protrusion of the bulb, and for widening of the space between the lids. The so-called cilio-spinal centre of Budge in the lower cervical cord is not automatic. Lastly, the channels by which excitation of the sciatic nerve acts reflexly on the pupil passes upwards along both lateral columns.

Peripheral Nerves: Visceral Nerves.—Vulpian has performed some experiments to determine the central origin of the glandular and vaso-dilator nerve-fibres of the chorda tympani and the glosso-pharyngeal. In curarised dogs under artificial respiration the nerves were stimulated in their course between their exit from the central nervous system and their passage through the base of the skull. It was found that stimulation of the trigeminus caused no secretion from the salivary glands or dilatation of the vessels of the mucous membrane of the tongue. Stimulation of the facial caused a flow of saliva from Wharton's duct, and with a strong stimulation, there was reddening of the anterior two-thirds of the mucous membrane of the tongue. With stimulation of the glosso-pharyngeal, the parotid gland secretes, and there is dilatation of the vessels of the mucous membrane of the tongue behind the crescent of the circumvallate papillæ. Vulpian concludes that in the chorda tympani the fibres of taste and the vaso-dilator for the anterior two-thirds of the tongue, and those of secretion for the submaxillary and sublingual glands, all come from the facial and depend for their nutrition on the ganglion geniculatum; while the fibres for the parotid gland and the vaso-dilators for the posterior third of the tongue come direct from the central nervous system with the glosso-pharyngeal, and do not enter the nerve by later anastomoses as has been thought by some. The most important research in this region of physiology published during the past year is that of Gaskell on visceral nerves; a research which marks an epoch in the study of the influence of the nervous system on excitable tissues. Gaskell shows that in the dog, visceral nerves leave the spinal cord in definite cervical, thoracic, and sacral regions; and may be recognised in the anterior roots of the spinal nerves as the smallest medullated fibres (about one-seventh the size of the largest). He considers that vaso-motor fibres leave the cord only in the thoracic region and enter the chain of sympathetic ganglia, which might more correctly be termed the chain of vaso-motor ganglia. For fuller details of the anatomy, the original must be consulted. From his experiments Gaskell has formulated a theory which he considers is of general application to the action of the nervous system on the heart, on vessels, on the movements of hollow viscera, and on the glandular structures. At the present time the theory applies chiefly to involuntary muscular tissue. The theory is this: All involuntary muscle-fibre is supplied by two sets of nerves, one of which (katabolic) increases tissue-change which accompanies functional activity, the other of which (anabolic) diminishes tissue-change and may be considered as constructive. Thus in the heart, the vagus fibres which cause inhibition of the heart would be anabolic, and the sympathetic fibres, which augment the beat, would be katabolic. The same mode of reasoning applies to the nerves of the blood-vessels and hollow viscera. It will be noticed that in this theory the nerves are supposed to retain their separate functions (whether of katabolism or of anabolism) right up to their termination in the tissue, and thus the supposition of the existence of peripheal centres in the heart, vessels, etc., is unnecessary. How far the theory will hold good for all the structures mentioned remains yet to be seen.

Digestion and Nutrition.—Ellenberger and Hofmeister have investigated the gastric juice of the pig, and the histology of the stomach. The left half (primary cardiac sac) of the glandular part of the mucous membrane contains short thick gland-tubes, with many surrounding lymph-follicles. In the right half, the fundus-gland region, the lumen of the glands is bordered by chief cells (hauptzellen), while the parietal cells (belagzellen) are in groups. The pyloric division of the stomach is rich in villi, but contains no parietal cells in the glands. The authors confirm for the pig, what is now generally accepted for carnivora, namely, that the parietal cells are acid-formers, while the chief cells are pepsin-formers. The cardiac sac produces no rennet ferment. Lewaschew has shown that in fasting dogs, the ferment-substance of the pancreas (trypsin) can disappear from the gland, while the zymogen-granules remain as thick as ever in the cells. This observation modifies Heidenhain's original view that the zymogen-granules were the ferment-formers; they can now only be considered ferment-carriers. This opinion is accepted by Heidenhain, in whose laboratory the work was done. Hanau has made some interesting observations on the quantity secreted by an isolated portion of intestine, the nerves of which have been divided. The animals (dogs) fasted twenty-four to thirty-six hours, and were fed four hours before the operation. The amount of secretion was found to equal $\frac{1}{30}$ to $\frac{1}{12}$ of the body-weight, or $\frac{2}{3}$ weight of the blood. The fluid secreted was at first clear, and then became turbid with clear epithelial-shreds. The secretion, like that from an intestine with intact nervous supply, had no digestive action or proteids. *Post mortem*, the portion of intestine was found dilated, lax like the intestine in an early stage of cholera. Some important experiments have been made on the movements of the stomach by Hofmeister and Schütz, and on those of the intestine by Cash; and the results obtained are likely to prove of great service. Hofmeister and Schütz investigated the automatic movements of the stomach of the dog by tying both ends, excising, and then suspending it in a warm chamber, in which the movements could be observed. The living stomach was found to be sharply divided into two parts, the larger one the cardia, the smaller the antrum pylori. In an empty stomach, a peristaltic wave begins at the cardia, and increases gradually as it extends along the great curvature. Then ensues the pre-antral contraction, which is a narrowing of the diameter of the stomach as the peristaltic wave reaches the margin of the antrum pylori. The peristaltic wave and the pre-antral contraction are together called the first phase of the "peristole." Following this first phase is the contraction of the antrum pylori, not peristaltically, but together, after which the pyloric sphincter itself contracts. The use of the contraction of the antrum is to drive the contents of the stomach into the duodenum; but if there are large solid particles in the liquid contents, instead of passing through the pylorus, there is an anti-peristaltic wave produced which drives the food back towards the cardia. Schütz has applied this method of research to the investigation of poisons in the stomach, and has obtained interesting results. Cash's experiments are also very im-

portant. A Vella's fistula was made in dogs, that is, a loop of intestine completely isolated, and with both openings stitched to the abdominal wall. By means of small bodies, to which a string attached to a lever was tied, a record could be obtained of the rapidity of peristaltic action. It was found, that during hunger there were periods of complete quiescence of the intestines; that after food regular peristaltic movements set in, and fell to a minimum in four to five hours. The act of swallowing, mental impressions, exercise and mechanical irritation of the fistula, all tended to excite peristalsis. Hofmeister, who had previously adduced experiments to show that peptones were absorbed by means of the lymph-cells in the mucous membrane, has extended his researches into a careful examination of the lymphatic plexuses in the gastro-intestinal mucous membrane. Important experiments have been published by Von Schroeder on the formation of urea in the liver. He had previously shown (and was confirmed by Salomon) that during the passage of ammonium carbonate and of the ammonium salts of easily oxydised organic acids through the portal system of an excised liver, there was a transformation into urea. He has now performed experiments on living dogs which showed that excision of the liver and kidneys stopped this transformation, whereas excision of the kidneys alone was powerless to do so. Also if the right kidney be excised, and the hepatic and the left renal arteries tied, and the portal vein united with the left renal vein by a glass tube, so that all the blood from the intestines passes through the kidney, it is found that the injection of ammonium salts does not lead to the formation of urea. It is concluded that this change occurs in the liver, and it is interesting that in an animal with an excised liver ammonium salts act as much more powerful poisons than in the normal animal. Side by side with these conclusions the experiments of Minskowski are important. After extirpation of the liver or ligature of the hepatic vessels in geese, he found that diuresis was produced, but that the amount of uric acid was diminished to $\frac{1}{10}$ to $\frac{1}{20}$ that of normal, while a large quantity of ammonia was excreted, five or six more times more than normal. He concludes that in geese ammonia is the precursor of uric acid, and that the transformation takes place in the liver; further, since urea subcutaneously injected appeared as urea in the urine, the transformation into uric acid which normally occurs in birds must take place in the liver. Other interesting facts were observed. There was no leucin or tyrosin in the urine, and sugar given to the animal caused the appearance of sugar in the urine. Sarcolactic acid was present. There is no doubt, from these series of observations, of the formation of uric acid by the liver in birds. Eröss has investigated the temperature in the rectum of 100 children, from birth and up to eight days of extra-uterine life. The average temperature at birth is 37.6° C. (99.7°Fahr.); it is lowered 1.7° C. during the first two hours, the average temperature during the first day being 36.47° C. (97.7° Fahr.). On the second day the average temperature is 37.18° C. (99° Fahr.), and on the eighth day, 37.16° C. (nearly 99° Fahr.). The rise on the second day is considered to be due to increased tissue-change; it is accompanied by loss of weight.

Glandular System.—Rogowitsch has experimented in Tschirjew's laboratory (Kiew) on the results of extirpation of the thyroid gland in dogs. He confirms Schiff and others as to the rapidly fatal result of the operation, ascribing it to "encephalo-myelitis parenchymatosa subacuta." The animals become apathetic, then have shivering and convulsive attacks, while there is difficulty of breathing and diminution of cutaneous sensibility. In animals that live three to four weeks there is cachexia and general paralysis. The changes found *post mortem* are engorgement of the vessels of the nervous tissue, with infiltration of the sub-adventitia with round cells. There is round-celled infiltration of the nerve-tissue itself, and swelling of the axis-cylinder and of the nerve-cells, which lose their contour and finally disappear. The grey substance is chiefly affected. The hypophysis cerebri is gorged with blood and the cells are in a state of colloid degeneration. There is no great diminution in the number of red corpuscles in the blood. An important fact is that when only one lateral lobe of the thyroid is excised the remaining portion of the gland undergoes hypertrophy after a time, with proliferation of epithelial cells and the formation of alveoli.

MEDICAL CHEMISTRY.

General Nutrition.—Proteids.—Digestion: Juices, Absorption, etc.—Blood.—Tissues and Organs.—Urine.

In our brief notes of the more important advances made in physiological and pathological chemistry since our last report, we shall follow more or less closely the order there adopted, and in doing so we may reiterate the remark then made of the impossibility of doing anything like justice to the subject in the space at our command—a remark, we may say, that applies even more strongly to this than to last year's work.

General Nutrition.—In a paper on the effects of minute quantities of inorganic salts on organic structures, Dr. Ringer states that lime lessens the amount of fluid that algin (a substance obtained from some of the commoner species of marine algæ) can imbibe, probably by combining with it. And while the effect of lime is to lessen the swelling of this vegetable-tissue compound, it likewise exercises a somewhat similar influence on certain animal products. His experiments with muscle make it appear that lime and potash salts are as necessary to the metabolism of muscle at rest as during activity. Active contractions are to be noticed in muscles placed in saline solutions, and when these cease, contractility still persists, and may readily be excited by the addition of substances like boric chloride.

North has continued his valuable series of researches upon the influence of bodily labour on the discharge of nitrogen. His results confirm those of Parkes, but he states that the disturbance produced by very severe labour is more immediate and more intense than was observed by Parkes. Retention of nitrogen followed the diminution of the nitrogen stored in the body produced by privation of nitrogenous food; and when, as the result of severe labour, the nitrogenous store was diminished, a corresponding diminution occurred in its discharge. This store of nitrogen is more constantly operative than is generally supposed. No increased phosphatic excretion ensued unless the work was very severe, the discharge of sulphates remaining proportional to that of the nitrogenous material.

It has been proved that part of the fat deposited in the bodies of pigs and geese is formed from the hydrocarbons of the food. Max Rubner's recent experiments appear to prove that the same holds good of the carnivora.

Proteids.—Schützenberger's researches lead him to regard albumen as formed by the union of one molecule of leucin with one molecule each of leucin, amido-valeric acid, and oxalic acid, and two molecules of ammonia, water being eliminated.

A characteristic new albumen reaction is described. If to one gram of albumen solution containing one part per million and a drop of formic acid, one drop of a solution of chloride of gold is added, a rose-red colour is obtained, with two drops a clear red, and with a third drop a blue colour.

Flour kept in sacks for some time shows traces of alkaloids, which gradually increase in quantity. When 12 to 18 months old, it yields sensible amounts, and the extract administered to sparrows kills them after a few hours, fresh flour giving no such results.

Mucin is soluble in dilute alkalies, precipitable therefrom by acetic acid, and when treated with dilute sulphuric acid yields a reducing substance, which Loebisch holds to be a carbo-hydrate, and the mucin itself a glucoside. Boiling renders the mucin no longer precipitable by acetic acid. Unlike the mucin from saliva and snail, tendon-mucin is not changed into coagulated proteid by boiling or by remaining under alcohol. The amount of mucin may be estimated not only by weighing the dried acetic acid precipitate, but likewise by the diminished alkalinity of the alkaline solution used to dissolve it, mucin itself possessing an acid reaction.

From experiments with cobra venom, Wolfenden concludes that its toxicity is not due to bacilli, alkaloids, or the hypothetical cobric acid, but that it depends solely on the proteid constituents present. These are globulin and an acid albumin, both of which probably kill by interfering with the respiratory mechanism; also a serum-albumin, likewise toxic, by producing a kind of ascending paralysis. In dubois poison the same proteids are present.

The power of the venom in all these snakes appears, then, to reside in the proteids, which certainly seems remarkable; for why should they, in these cases, be so strongly poisonous? The proteid molecule, however, is still but little understood, and accordingly it is not unreasonable, as the author suggests, that in some cases its arrangement may produce a poisonous body. In peptone itself we have an example of a toxic proteid, since injections of this body into the circulation have been shown by Schmidt-Mulheim to reduce the blood-pressure rapidly and remarkably. And some viper poisons appear to do the same. Indeed, there seems no antecedent improbability in the supposition that a rearrangement of the albumen molecule, without altering its ultimate composition, and without depriving it of its typical class characters, should make it poisonous. The truth is, our knowledge of the proteids is still but fragmentary.

Meat peptones owe much of their value to the large amount of extractives and salts they contain. Kuhne has recently shown that commercial peptones consist largely of albumoses; while clinical experience tends to prove Kemmerich's peptone to be more nourishing than Koch's; and, according to Pollitzer, peptone and hemi-albumose

appear to have the same nutritive value as it is. As to the physiological action of peptones and albumoses, Pollitzer has contributed some rather startling facts. Pure solutions of these bodies were employed containing 5 per cent. of the proteid and ½ per cent. sodic carbonate, which were injected into the external jugular and femoral veins of dogs at a temperature of 40° C. The results of the experiments were these: (1) All of them employed, with the exception of anti-peptone, exercised a strong narcotic action, a stage of excitement followed by manifestations of pain and distress being succeeded by narcosis, resembling that produced by chloroform. There was no motor paralysis, and the reflexes were unaffected. (2) The coagulation of the blood was either delayed or entirely prevented. It had already been found by Schmidt Mulheim, when he caused blood to flow into a vessel containing an equal portion of blood from another dog into whose veins an injection of peptone had been made, that the coagulation of the whole was prevented. Pollitzer corroborates him in this; but, on the other hand, he obtained coagulation when the blood was allowed to flow into ½ per cent. solutions of sodic carbonate containing one-fifth gramme of the different proteids. (3) Immediately after the injection the blood-pressure sank to a degree which would have been fatal to the animal, had it continued at its lowest point for a considerable period. This fall in pressure was due to vaso-motor paralysis, the splanchnic region being that chiefly affected. While a sufficiently large dose of any of the albumoses (a little more than ·3 gramme per kilo.) was inevitably fatal, peptone never produced this result so long as the kidneys were intact.

To obtain pure peptone, Kühne and Chittenden saturate artificial gastric juice with ammonic sulphate (which precipitates all the proteids, with the exception of peptones), by which means mucin and pepsin are thrown down; the pepsin is then dissolved up with dilute hydrochloric acid, and this solution they use as the digestive fluid. The pure peptone obtained by its means behaves with water like phosphoric anhydride, hissing, and evolving heat; it forms a brown, watery solution, has a cheesy but not unpleasant taste, and is precipitable by tannic, phosphotungstic, and picric acids.

Digestion: Juices, Absorption, etc.—Goldschmidt states that an active ferment is not pre-formed in the salivary glands, and that not only is sugar formed by the action of saliva, but also a certain amount of fatty acids, especially lactic.

According to Sundberg, a saturated solution of sodium chloride is the most advantageous means for obtaining pepsin from the mucous membrane of the stomach, free from proteids. The stomach, with the exception of the pyloric end, is rubbed up with a weighed quantity of the salt, and enough water is added to obtain a saturated solution. The whole is filtered after two or three hours, and the chloride removed by dialysis into acidulated water. To obtain the pepsin in a very pure state, it is precipitated from the acid solution by a mixture of calcic chloride and sodic phosphate; the precipitate collected, well washed, decomposed with hydrochloric acid, and then dialysed. In this way a very active pure pepsin is obtained, which is not precipitated by tannin, mercuric chloride, or the neutral or basic acetates of lead, all of which throw down Brücke's pepsin. The only reagent that acts as a precipitant of the new pepsin is absolute alcohol.

Schumberg corroborates previous investigations indicating the presence of a special milk-ferment in human gastric juice, whose activity is suppressed by sodic carbonate, but increased by hydrochloric acid. The diastatic action of this juice is ascribed by Hofmeister to the imbibition of the swallowed saliva by the gastric mucous membrane, in which it can be detected in the pyloric region. Ewald and Boas have detected the constant presence of lactic acid in the human stomach, as well on a meat as on a vegetable diet. It was only wanting when pure albumen alone was ingested. But, while they regard this acid as normally present, they ascribe it to an habitual but non-pathological fermentation.

Under Grützner's direction, Podwyssozki has found that pepsin is met with in the gastric mucous membrane under three forms: ordinary pepsin, soluble in glycerine and hydrochloric acid; propepsin, soluble in the same reagents, but without direct action on proteids, readily changed, however, into ordinary pepsin by the action of hydrochloric acid; and another variety of propepsin, insoluble in glycerin, but soluble in hydrochloric acid, and equally transformed thereby into ordinary pepsin. The amount of pepsin and propepsin is considerably augmented by allowing the mucous membrane to be exposed to the air for twenty-four hours. Change of the propepsin into pepsin occurs, and new quantities of propepsin seem to be formed. The most active extract, indeed, is prepared by exposing the stomach to the air for twenty-four hours (using camphor or salicylic acid as an antiseptic), and then treating the mucous membrane with hydrochloric acid (1/10 per cent.).

When a diet containing no chlorides, as powdered meat thoroughly washed with distilled water, is given to an animal, the chlorides disappear from the urine, and hydrochloric acid is absent from the gastric juice, although the formation of pepsin continues. But when carbo-hydrates are supplied with the washed meat, lactic acid is formed, and so peptonisation occurs.

Chandelon has shown that peroxide of hydrogen possesses the power of transforming albumen into peptones. The activity of trypsin he attributes to the oxygen generated. Now, according to Podolinsky, a solution of pepsin loses its digestive power when it is submitted to beer yeast, that is, when its oxygen is removed; and the pepsin thus rendered inactive has not its activity restored by the action of oxygen, although pepsin rendered inactive by carbonate of soda recovers its activity under the influence of a hydric peroxide solution but not by the action of oxygen alone.

A subcutaneous injection of pilocarpin increases the salivary and pancreatic secretions. In animals who have been starved for twenty-four hours, the yield of trypsin was abundant, but if starved for a longer period no trypsin was obtained, and yet here the so-called zymogen granules were found in abundance in the cells of the pancreas. These granules would therefore appear not to be zymogen themselves, but only carriers of it (Heidenhain, etc.).

Some recent work by Wenz throws considerable doubt on the power of intestinal juice to peptonise albumen. The intestinal mucous membrane was subjected to prolonged washing with various agents, thymol being used to prevent putrefaction. The experiments were made with loops of dogs' intestines after Thiry's plan, and the method adopted to detect the peptones was to shake the fluid with ammonic sulphate in excess, and test the filtrate for peptone by the biuret reaction.

It has already been maintained by Hofmeister that the absorption of peptones in the intestine is not a purely mechanical phenomenon of diffusion or filtration, but that it represents a function devolving on the leucocytes, which play, in relation to the assimilation of proteids, a part analogous to that performed by the red corpuscles in the respiratory function. He further maintains that the peptone is not in a free state in the blood, but is combined with the cells, by whose instrumentality it is carried to the places where it is assimilated; and that these leucocytes have their origin in the adenoid tissue of the intestine, particularly in Peyer's patches, the richness in young cells being directly proportional to the nutritive activity. The peptone, Hofmeister believes, combines with the nuclear substance of the cells; for he finds that it is possible to transform, in a very simple manner, peptone and hemi-albumose into a substance closely related to the nuclein group. The assimilation of the peptones and their transport to the elements of the organs being thus dependent on the lymphatic cells distributed on the deep surface of the mucous membrane, it would necessarily follow that the adenoid tissue ought to be most largely represented at those portions of the intestinal tract, where the absorption of peptones attains its greatest activity; and this Hofmeister has found to be the case.

In the artificial pancreatic digestion of proteids putrefaction readily occurs, indol, skatol, phenol, and oxy-acids being formed; but the presence of small quantities of carbo-hydrates entirely prevents this. In experiments with dogs it was found that, upon a flesh diet, mixed with sugar, starch, or glycerine, the formation of putrefactive products was lessened, although not completely prevented.

Blood.—Halliburton finds that while the proteids of the blood of birds resemble very closely those of mammals, the proteids of the blood-serum of cold-blooded differ from those of warm-blooded animals by their percentage being smaller, by the absolute and relative preponderance of the serum globulin over the serum-albumen, and by their serum-albumen seeming to consist of a single proteid.

According to Ehrlich the stroma of the red corpuscles plays an important part by hindering their dissolution, by preserving the hæmoglobin of a normal oxidation, and by opposing their penetration by different principles contained in the blood. It is the stroma which constitutes the protoplasm or discoplasm of the cell, the hæmoglobin the paraplasm; and by analogy of what passes in other cells we may admit that the hæmoglobin is formed at the expense of the stroma by endogenous production. This would explain the poverty in hæmoglobin of old or dyscrasic corpuscles.

Von Stein prepares blood crystals by defibrinating the animal's blood, or allowing it to coagulate and then expressing the clot. A drop of the serum thus obtained is placed on the slide, and when its borders begin to dry it is surrounded with Canada balsam, and afterwards covered with more of the same. The balsam must not be too liquid, but should have the same refractive index as the glass, and be dissolved in essence of cloves. The decomposition of the corpuscles is hastened by the active ozone in the turpentine.

Nencki and Sieber have succeeded in obtaining reduced hæmoglobin in a crystalline form. Crystallised oxyhæmoglobin of horse's blood is dissolved in water, to which some putrid blood is added, and the whole placed in an atmosphere of hydrogen, and then exposed to a temperature of 25° C. for eight to fourteen days. It is next allowed to cool down and absolute alcohol is introduced to the extent of about 25 per cent., and the mixture left for twelve to twenty-four hours at 5° to 10° C. Crystals of reduced hæmoglobin are deposited on the walls of the vessel in the form of six-sided prisms, which are doubly refractive, give the single absorption band, present a reddish violet tint, and when exposed to the air for some time show the double oxyhæmoglobin band.

MacMunn has demonstrated the presence of hæmatoporphyrin in the integument of certain invertebrates (slugs, etc.) This body possesses a characteristic spectrum in the acid and alkaline conditions respectively; but just as there are several hæmoglobins, so there are many hæmatins and hæmatoporphyrins. There are, in fact, classes of colouring matters presenting bands similar but not always identical in position.

In a series of recent papers Seegen has again taken up the questions as to the presence of reducing substances in the blood insusceptible of fermentation, the influence of alimentation on the quantity of sugar contained in the blood, and the physiological and pathological factors in diabetes. He denies Otto's conclusions, and maintains that the reducing substances in the blood are formed almost exclusively of dextrose; but that to obtain an accordance in the results of fermentation with those of polarisation and reduction, the fermentation must be allowed to continue for several weeks, as the blood-sugar ferments with excessive slowness. Most physiologists admit, with Bernard, that the sugar of the blood is formed in the liver by the transformation of the hepatic glycogen; but Seegen is opposed to this opinion, for, according to him, although sugar is formed in the liver it is not at the expense of the glycogen. To precipitate the albuminous matters of the blood before titrating for the sugar, Seegan recommends the use of acetate of iron. In all his experiments the blood of the hepatic was found to contain more sugar than that of the portal vein. This formation of sugar in the liver is not interrupted by a prolonged fast, but it is increased by a diet rich in carbo-hydrates. Among diabetics some fabricate their sugar at the expense of the proteids of their organism, others at the expense of the feculent material in their food. Seegen questions the existence of a sugar ferment in the liver. The hepatic tissue itself possesses a feeble diastatic power, just like all soluble proteids, egg albumen, and casein. He further maintains that the variations in the amounts of glycogen and sugar in the liver are independent of each other. After death, the sugar continues to be formed; its quantity augments, but the glycogen does not diminish proportionally. The sugar formation is a physiological phenomenon associated with the life of the hepatic cells. Immediately after death the quantity of sugar found in the liver is remarkably constant (0.4 to 0.6 per cent.). While denying the sugar to have its source in the glycogen, he believes it to have it in the peptones, the liver also possessing the power of transforming fat into sugar. In animals fed on peptones the sugar increases greatly; and by placing a piece of liver in a solution of peptone for some time, the quantity of sugar present is found to be 70 per cent. greater than in a similar fragment immersed in water. After many failures Seegen succeeded in establishing a constant diminution of the sugar in the blood as the result of an ablation of the liver.

From the testis and thymus gland Wooldridge has obtained a proteid body the injection of which into the veins of an animal caused instant death from wide-spread intravascular clotting.

As a constant result of a septic febrile condition in dogs, a diminution of the carbonic acid in the arterial blood occurs, lasting during the febrile condition. Minkowski asserts that this is due to a diminished alkalinity of the blood, which he ascribes to an increased production of acid bodies in the febrile state, during which, although the oxidations are more active, the products are different from those formed normally. But the diminution in the carbonic acid is not proportional to the internal temperature in the septic fever, nor is it an immediate consequence thereof, an accelerated respiration and modified nutritive exchanges intervening.

The following test for blood has been highly recommended as being more delicate and certain than Teichmann's. Make a watery extract of the blood stain, add to it a drop of tincture of iodine and a drop or two of acetic acid, and place a drop of the mixture on a glass slide, which is to be repeatedly passed through a flame, eight to ten drops of acetic acid being gradually added. Crystals of iodohæmin will make their appearance with absolute certainty in one to two minutes.

Tissues and Organs.—Nuclein was the name given to a substance found by Miescher in the yolk of egg. Kossel has compared this body with the nuclein of cell nuclei, but finds they are not identical. During development the egg nuclein becomes capable of producing bases rich in nitrogen, such as guanin, hypoxanthin, and adenin.

Zillner concludes that adipocere is formed from the various fats present in the body at the moment of death, and that the albuminoids take no part in this transformation.

The chlorides of rubidium and calcium act upon striated muscle in the same manner as the potassium salt, but the paralysing action is less pronounced, calcium being less active than sodium in this respect. The alkali metals, accordingly, considered in respect to their depressing action on the contractility of striated muscle may be arranged in a descending scale, extending from potassium to lithium; rubidium, calcium, sodium, and ammonium forming the intervening members (Harnach and Dietrich).

In the white substance of the sciatic nerve Chevalier found much lecithin and little cerebrin. This was the percentage obtained: cerebrin, 11.30; lecithin, 22.57; cholesterin, 12.22; albumen, 36.80; neurilemma, &c., 4.04; neurokeratin, 3.07.

Many years ago Schmiedeberg ascribed the arrest of the heart produced by muscarin to its property of exciting the inhibitory ganglia in the heart wall. This view was opposed by many observers, but in an admirable paper Kobert has recently maintained the exactitude of Schmiedeberg's original interpretation, the contrary results of other observers being attributable to the use of impure muscarin.

The differences in the irritability of normal muscle in its different parts are due to irregularities in the distribution of its motor nerves, and as these differences persist after curarisation, it seems certain that curare leaves certain terminal nerve elements in the muscle unaffected. Pollitzer supposes that the curare acts on the nerves at the points where the axis-cylinders are most exposed—that is, at the nodes of Ranvier, and in the first place on that particular node most exposed to the poison-bearing lymph currents—that is, the last; and that it is not the axis-cylinders themselves but the cement substance at the nodes upon which the drug exercises its specific action.

Von Schroeder has already proved that while the muscles and kidneys cannot transform carbonate of ammonia into urea, this power is possessed by the liver. The transformation, he further finds, takes place rapidly, but it will not occur at all if the liver is withdrawn from the circulation. It had been previously demonstrated by Minkowski that in animals deprived of their liver the excretion of uric acid diminishes rapidly, while ammoniacal salts are eliminated in great quantities.

Two methods have hitherto been adopted for the removal of glycogen from liver and muscle: extraction with hot water and with hot potash, the proteids being precipitated by hydrochloric acid and potassio-mercuric iodide, and then the glycogen by alcohol. Külz finds that the potash-extraction method is quicker and more thorough, and causes no loss of glycogen in the process of extraction. When an artificial mixture of glycogen and white of egg is similarly treated, it is found that 12 per cent. of the glycogen is thrown down with the proteid, although no such loss occurs during the similar precipitation of proteid in a potash extract of liver or muscle.

Urine.—The acid reaction of urine is due to the excess of acid over normal phosphates. The ratio of the phosphoric anhydride combined as normal phosphate to that as acid phosphate is the following: evening urine, 91:100; night urine, 56:100; morning urine, 58:100; or for the urine of the twenty-four hours, as 69:100.

Hypobromite solutions do not keep well, and accordingly Lunge has recommended the use of A. Frank's bromum solidificatum. The solution is thus prepared: 400 grammes of caustic soda are dissolved in a litre of water and kept in a stoppered bottle. To 100 cubic centimètres of this solution about 100 grammes of bromine, that is to say, 10 centimètres of the stick of the brom. solid. are added. When the stick is decolorised the solution can be employed.

On the relationship of the formation of urea and uric acid to the secretion of bile some interesting papers by Noel Paton will be found in this year's JOURNAL, to which we must direct the reader. Suffice it here to say that the author establishes a direct relationship between the urea formation and the biliary secretion.

Albuminuria.—The temperature, according to Loewy, exercises a marked influence on the composition of filtered liquids. The quantity of the filtrate increases with the elevation of temperature. He agrees with Senator in regarding the albuminuria occurring in certain febrile conditions as due to the elevation of temperature.

The effect of compression of the thorax has been studied by Schreiber, according to whom a slight temporary albuminuria is the result, its degree being increased with the duration of the compression. Serum albumin and globulin were the albumins met with. Schreiber

concludes that dyspnœa was not the cause of the albuminuria, but that the factors are: the diminution of the difference of pressure normally existing between the alveolar capillaries of the lung and the left ventricle; the diminished calibre of the pulmonary vessels, and the diminished extent of the respiratory excursions. A stasis in the pulmonary circulation is thus produced which is rapidly propagated to the renal capillaries, with consequent filtration of albumen. In young subjects (eleven to fifteen years) a thoracic compression lasting half a minute has sufficed to cause the appearance of albuminuria, of which there were no traces an hour subsequently.

Biliary Urine.—Oliver has proposed the following delicate test for the biliary acids. The solution is prepared thus: peptone in powder, 1.80 grammes; salicylic acid, 0.24 gramme; acetic acid, 60 drops; distilled water, 240 cubic centimètres. One part of urine containing biliary salts in a pathological proportion when added to three parts of this reagent causes the appearance of an opalescence, which disappears on the addition of one or two drops of acetic acid, but not on boiling. The urine should be transparent; if it contains urates in excess it should be warmed; if muddy from phosphates it is to be slightly acidified with citric acid, or filtered; if blood or albumen is present it is to be boiled and then filtered; and it is further advisable to reduce the density of the urine to 1008.

Sugar.—Two delicate tests have been proposed. A solution of hydrochloride of phenylhydrazine, containing sodic acetate, gives a yellow crystalline precipitate. By this test sugar is never found in normal urine. If much albumen is present it should first be separated. A more delicate test still is the following, by means of which sugar can always be detected, even in normal urine. A small quantity of the saccharine solution is mixed with two drops of an alcoholic solution of naphthol or thymol, and an excess of strong sulphuric acid added; a deep coloration is produced, violet with the former and red with the latter. The test is of especial value for microchemical examinations.

Pigments.—The physician's attention should be directed solely to two urinary pigments, urobilin and indican, as the existence of other pigments is doubtful, and their significance equivocal. Cervesata has published some interesting conclusions as to urinary indican, of which we shall briefly summarise the chief. Normal urine contains uro-indican, whose artificial or spontaneous decomposition gives rise to indigo. To detect the indigo blue, it suffices in most cases to employ sulphuric acid and chloroform; but it is always useful to treat the urine previously with basic acetate of lead, particularly when it is scanty, dense, and high-coloured. The sulphuric acid is preferable to the hydrochloric, because the reaction occurs more readily and more markedly, and is less liable to error. Vierordt's spectrometric method is recommended for its determination. In individuals in good health the indigo is found in very small amount, increasing, however, under a meat diet, but to a greater extent if aromatic compounds are administered; fasting, on the other hand, causes its diminution. Its elimination is greatly increased in diseases in which inanition and marked tissue-waste are prominent factors; also in diseases of the abdominal organs, particularly of the intestine; in many nervous affections, in splenic anæmia, renal cirrhosis, diabetes, and chronic lead poisoning. On the other hand, its elimination is very slight in fevers, parenchymatous nephritis, chlorosis, scrofula, advanced phthisis, catarrhal jaundice, hepatic cirrhosis, and ovarian tumours. The variations in its elimination are probably to be attributed to nervous modifications of the pancreatic secretion.

Aromatic Constituents.—Baumann has tried to determine the relationship between the putrid fermentations occurring in the intestine, and the formation of the sulphovinic and oxy-acids. From experiments on a patient with intestinal fistula he was led to conclude that when the putrefaction diminished in the intestine, as after the administration of calomel, the sulphovinic acids diminished equally in the urine.

A concentrated solution of picric acid produces a slight crystalline sediment in normal urine after an hour or two. Jaffe finds this to be partly uric acid and partly a double salt of kreatinin picrate with potassic picrate. It forms, indeed, a delicate test for kreatinin, giving a deep red colour with dilute solutions in the cold.

Alkaloids.—To detect these the reagent employed is thus prepared: iodine, 8; potassic iodide, 10; water, 10. Cool the urine to 0° C., after adding a few drops of the reagent; then concentrate a bright light by mean of a lens on the urine in a test tube placed against a dark background. The green fluorescence is readily seen. It can thus be shown that the proportion of alkaloids in the urine passed during the eight hours after waking is five times as great as in the urine of the rest of the day.

Toxicity.—Bouchard has continued his researches as to the toxicity of normal urine. Man, even in a normal condition, is constantly destroying and excreting poisons either introduced into or formed in the organism, and the urine is one of the chief sources of elimination.

After an intravenous injection of normal urine, there is contraction of the pupils followed by quickened shallow respirations and muscular weakness. The urinary secretion augments and the temperature falls. Death happens generally without convulsions, the animal dying most frequently in a state of coma. The quantity of normal urine necessary to destroy the life of a kilo of living tissue is very variable, oscillating between 10 cubic centimètres and 122 cubic centimètres per kilo, but 45 cubic centimètres may be taken as the mean in an adult. A man requires about two and one-sixth days to fabricate the quantity of urinary poison capable of poisoning himself, a co-efficient, it may be said, which varies little in health, but greatly in disease.

The urine secreted during sleep is less toxic than that of the waking period. The character of the poison eliminated in the two periods also differs greatly, that of the waking period being narcotic in its properties, and that of sleep being convulsive. During the former, therefore, the body produces a substance which, accumulated, will induce sleep; during sleep, on the other hand, it elaborates a convulsive principle, which, when it accumulates, would tend to produce muscular irritation and provoke wakefulness. The variations in the toxicity depend especially on the greater or less intensity of the oxidations; with increased muscular activity, for example, during which more oxygen is consumed, the toxicity is lessened.

Feltz has experimented with febrile urine, and he finds that it is much more toxic in its properties; and, further, that there is no proportional relation between the density of the urine and its toxicity, as is the case with normal urine. There must, therefore, be other toxic agents in febrile, than are to be found in normal urine.

According to Lépine and Aubert the special toxicity of febrile urine seems to be due to its organic rather than its saline constituents, as has been affirmed by some authorities; and, contrary to Bouchard and Pouchet, Villiers finds that normal urine never contains alkaloids, although these were present when the patient was suffering from febrile or inflammatory affections. Rovighi, again, like Feltz and Ritter, concludes from his experiments that uræmia is essentially determined by the salts of potassium, and that the uræmic convulsions are caused by an accumulation in the blood of inorganic salts, and more especially of those of potash.

PATHOLOGY.

Rhinoscleroma. — Tetanus. — Pleuropneumonia. — Glanders. — Pneumonia.—Cholera.—Injection of Micro-organisms into Blood.—Spread of Epidemics.—General Laws of the Infective Process.—Drinking Water.

In the department of bacteriology there are no new and startling discoveries to chronicle. The work which has been done has been rather in the way of studying the characteristics and life-history of the bacteria already known than of discovering new ones. The following is a brief summary of the most important and trustworthy researches.

Rhinoscleroma.—The presence of bacteria in rhinoscleroma was first demonstrated by von Frisch, and has since been confirmed by various observers. Paltauf and von Eiselsberg have succeeded in cultivating these organisms and in studying their characters, and their conclusions may be summed up as follows:—In the tumour-substance well characterised bacteria with capsules were constantly present in six cases examined, and from all these cases pure cultivations of the same species were obtained. No other organisms were found. These bacteria closely resemble Friedlaender's pneumococcus in form, mode of growth, and effect on the lower animals. The authors did not succeed in producing a disease similar to rhinoscleroma in the animals experimented on; nevertheless, they conclude from the facts of the constant presence of the organisms, of their large numbers, and of the absence of other kinds, that they are the cause of the disease. They succeeded in cultivating this bacterium, not only from the tissue of the growth, but from the nasal secretion in one case. They think that the disease is essentially a chronic inflammatory affection, and that it is generally preceded by long continued ozæna, or discharge from the nose, caused by the organisms in question. They do not look on this bacterium as absolutely identical with Friedlaender's pneumococcus; but as very closely allied to it—in fact, a variety of the same species; it is not so virulent as Friedlaender's organism.

Tetanus.—Experiments were published some time ago by Nicolaier, and are still being continued by Flügge, which showed that many specimens of earth contained bacilli which, when introduced beneath the skin of rabbits or mice, set up tetanic symptoms and death. These

bacilli were anaerobes, and spore-bearing, the spore being formed at one end of the rod. They have been grown in blood-serum, and when bits of thread are impregnated with the cultivation, and introduced beneath the skin of rabbits, the tetanic symptoms follow. The usual place selected for inoculation is over one of the thighs; in twenty-four to thirty-six hours the leg on that side is found to be rigid, this condition soon spreads to the leg on other side, and thence to the forelegs, and after this rigidity has lasted for some time the slightest jar or breath of air sends the animal into violent tetanic spasms. Inflammation does not occur at the seat of inoculation, and the bacteria only grow locally, and do not become diffused over the body. Rosenbach, at the meeting of the Surgical Congress last April, mentioned that in a case of tetanus in man, following a wound over the elbow, he had found the same bacilli in the wound; and he seemed inclined to think that they were the cause of the tetanus in his case. This subject certainly deserves further investigation.

Pleuropneumonia.—Polels and Nolen, in Rotterdam, have found a micrococcus in the pleuropneumonia of cattle which they consider to be the cause of the disease. This organism resembles Friedlaender's pneumococcus in appearance, and in the presence of a capsule; it also forms pin-head growths in gelatine, but these are cream-coloured rather than white. They were constantly present in the lungs and in the pleural exudation in all cases of recent pleuropneumonia, and when injected into the lungs of rabbits, guinea-pigs, dogs, and cattle, set up pneumonic alterations. Injection into the trachea of dogs, and inhalation of a spray of a cultivation, also set up pneumonia.

Glanders.—Loeffler has published in detail his investigations on glanders, and gives some very interesting facts, although the main results had been previously made known. As to the animals most liable to the disease, Loeffler has found that after horses and asses come goats and cats, and then sheep, rabbits, and guinea-pigs; swine and cattle are almost absolutely exempt. The bacilli are constantly present in the affected parts, though it is somewhat difficult to stain them distinctly. They are not present in the blood unless in the early stage of acute glanders, but as this is not the element in which they live, they are soon deposited in various organs. They grow readily in blood-serum kept at the body temperature, and from these cultivations animals can be readily infected with the typical disease. They also grow on potatoes, but if the cultivations are carried on for some time, the bacilli gradually lose their virulence. Loeffler believes that infection never occurs through the uninjured skin and mucous membrane, but only through wounds of the integument. He considers that the occurrence of infection from the intestinal canal is very improbable. He has also found that, in the case of one guinea-pig, the disease was hereditary.

Pneumonia.—A good deal of work has been done during the year in regard to the bacteria associated with pneumonia. Dr. Fraenkel published an elaborate research, carried out in 129 cases, of which eighty-three were tested by cultivation; and he found that the organism most frequently present was a diplococcus, an oval, lancet-shaped or round coccus growing in chains, and requiring a comparatively high temperature for its growth. This organism is apparently identical with Sternberg's micrococcus, and is frequently present also in the saliva of healthy persons. It produces a form of septicæmia in several of the lower animals. The same organism has been found in meningitis after pneumonia. Weichselbaum has found other pathogenic organisms: in nineteen cases he found a streptococcus of erysipelas; in five cases staphylococcus albus and aureus; and in six cases Friedlaender's pneumococcus. It remains to be determined whether Fraenkel's bacillus, as it is present in healthy saliva, may not be only secondarily engrafted on the pneumonic process. Dr. Manfredi has found in the sputum of pneumonia after measles, in two cases, not only Friedlaender's pneumococcus, but also a small micrococcus which has peculiar and fatal effects on several species of animals, notably on rabbits and guinea-pigs. Subcutaneous injection of cultivations of this organism into these animals is followed by the formation of an inflammatory swelling at the seat of injection, which rapidly reaches a considerable size, and has a marked tendency to break down and suppurate. The neighbouring lymphatic vessels and glands also become similarly enlarged, and on the third or fourth day small nodules, composed of granulation-tissue, are found in various internal organs, especially in the spleen and liver, and also to a less extent in the lungs. The animals die between the seventh and twelfth days after infection, and show the presence of the nodules, which have by that time attained a considerable size, and are undergoing degeneration in the centre in large numbers throughout the body. In the lungs, also, there is generally pretty extensive hepatisation, in addition to small numbers of the nodules. The micrococci are present in large numbers in the caseous centre of the nodules and at the margin; they are found chiefly in the interior of the cells. These observations require to be extended to other cases of this disease.

Cholera.—On the subject of cholera nothing new has been written, the various researches that have been made having only tended to confirm Koch's observations. The most important paper, as clearing away the difficulties raised by Emmerich's investigations, is one by Dr. Weisser, in the second number of the *Zeitschrift für Hygiene*. From a very elaborate research into the bacteria present in normal and abnormal human fæces and a careful comparison with the Naples bacterium, both as regards their morphological form, mode of growth and relation to animals, Weisser comes to the conclusion that bacteria are present in human fæces, normal and abnormal, in air, and in putrefying fluids which are identical with Emmerich's so-called Naples cholera bacteria in morphological appearance, in biological function, and in pathogenic action. Emmerich's assertion that these bacteria stand in an important etiological relation to Asiatic cholera is thus, in Weisser's opinion, proved to be erroneous.

Injection of Micro-organisms into Blood.—An important paper was published by Wyssokowitsch on the fate of micro-organisms when injected into the body of warm-blooded animals. In 1874, Traube and Gscheidlen found that, if a quantity of putrid fluid were injected into the blood of rabbits and dogs, and the blood taken twenty-four hours later, with aseptic precautions, no organisms developed in it, showing that the bacteria introduced had disappeared from the blood, or had been destroyed in it in that short time. Some years later, Watson Cheyne found also that saprophytic bacteria, when injected into the blood-stream of rabbits, disappeared from the blood in twenty-four or forty-eight hours, and he concluded that they had been destroyed in it. Pursuing the subject further, he found that, if larger quantities were introduced, along with the fluid in which they grew, they were able to survive for a longer time, and that the same was the case with smaller quantities, if the animals experimented on had been previously weakened in health by the administration of repeated doses of phosphorus or other poisons. He explained this fact on the supposition that the products introduced with the larger quantities of putrefying fluid, or the poisons previously administered, had so weakened the vitality of the blood and tissues that they were no longer able to destroy the bacteria. Wyssokowitsch has repeated the experiments, and has come in the main to the same conclusions as Watson Cheyne, but he has added several interesting observations. In the previous researches, mixtures of bacteria, probably not containing spores, were employed; but Wyssokowitsch used pure cultivations of known organisms, and found that, while sporeless bacteria were rapidly destroyed, the spores could retain their vitality in the body for a long time, and remained in the tissues in a dormant state. In both cases, the blood very rapidly became freed from organisms, but the spores were deposited chiefly in the liver, spleen, and medulla of bone, and were apparently taken up by the endothelial cells of the capillaries, in which they were found imbedded many days after their introduction. In one case a few spores of bacillus subtilis were found alive in the liver seventy-eight days after their injection, although none were present in the other tissues or organs. Wyssokowitsch's results with pathogenic organisms are very interesting. When only a few anthrax bacilli were injected, they disappeared from the blood almost completely for some hours, but after twenty-four hours they began to appear again, and increased in number till the death of the animal. When they were introduced in large numbers, this disappearance from the blood was not very marked. Apparently all bacteria tend to be deposited in the organs before mentioned, and in the case of non-pathogenic organisms are there rapidly destroyed unless spores are present. In the case of pathogenic bacteria, this deposit and destruction of the organisms is incomplete, and they very soon gain the upper hand, and again spread into and multiply in the blood. We have thus in the structure of the vascular walls, and especially in the endothelial cells of the capillaries, a protective arrangement against any bacteria which may find their way into the blood. These organisms are deposited and retained in or between the endothelial cells of the capillaries, especially in the organs in which the circulation of the blood is slowest. Then begins a battle between the cells and the bacteria, which results either in the destruction of the bacteria or of the cells, which in the latter case provide a pabulum for the further development of the organisms. Those bacteria which as a rule gain the victory must be looked on as specific bacteria, pathogenic for the class of animal experimented on.

Spread of Epidemics.—Although in many cases it is now definitively proved that the micro-organisms present are the cause of the disease, very little is known as to the modes of infection and the spread of epidemics, and accordingly the attention of several investigators has been attracted to this question. In the case of several diseases, such as

anthrax, typhoid fever, cholera, etc., Pettenkofer has strongly advocated their relation to the soil. He holds that a certain local and seasonable condition is essential to the spread of these diseases, and finds these two factors in a porous material, the soil, penetrable by air and water, and soaked with organic substances (local predisposition), and in variations in the moisture and temperature (seasonal predisposition). He teaches that the so-called contagious miasmatic infective diseases are in reality true miasmatic or soil affections. The virus is formed outside the body. The virus, *x*, leaves the body in an inactive condition; outside the body, in the ground or in a suitable substitute, something, *y*, is added to this inactive germ, and out of this combination, which occurs only outside the body, that is, out of *x* and *y* is formed the infective germ *z*. That this supposition is in part wrong, is now proved as regards anthrax and cholera, by the fact that the intestinal discharges from animals suffering from these diseases are capable of giving rise to them in another animal, showing that the infective material leaves the body in a thoroughly active condition. Nevertheless, when these and other similar diseases occur in an epidemic form, it must be admitted that there is some relation between the soil and temperature, and the spread of the disease. What this relation is has been the subject of investigation by Soyka, Hueppe and others. Soyka has examined the relation of bacteria to soil, taking especial note of the effect of moisture, temperature and air. He finds that when anthrax bacilli are placed on soil they rapidly develop spores, and thus provide for their future propagation, and that the rapidity and certainty with which this occurs depend on the degree of moisture, on the temperature, and on the access of air. The necessary conditions are present in nature during the greater part of the year, and it is in this way that the soil is so essential to the spread of this disease. For were it not for this effect of the soil, these bacilli would soon die out because they are quickly destroyed by the ordinary saprophytic bacteria, if they are not in the spore condition. The soil acts then not by adding to their virulence, but by providing against their destruction. Hueppe has made a special study of this matter in reference chiefly to an epidemic affection of deer caused by a small bacterium. Here Hueppe found that the only relation to the soil was, that the infection was generally intestinal, that the bacteria could vegetate luxuriantly outside the body, and were not killed in passing through the stomach. Pettenkofer looks on inhalation as the chief mode of infection, and in fact disregards infection through drinking-water. The researches of Hueppe and Soyka show that in this he is wrong, and that infection occurs probably most often through the food and drink. Each disease seems to have its special mode of infection, depending on the biological characters of the micro-organism which causes it.

General Laws of the Infective Process.—A very important research, also bearing on the conditions of infection, has been made by one of our Research Scholars, Mr. Watson Cheyne, and it was published in the JOURNAL of July 31st. In this research it was pointed out that the initial dose of virus was of great importance, and in several instances exercised a marked influence on the course and virulence of the disease. Various laws were made out—for example, the pathogenic dose of a virus varies inversely with the predisposition of the animal to the disease in question; in animals not very susceptible to a disease, the severity of the affection varies directly within certain limits with the amount of the virus introduced, etc. It was found that in some cases a small dose of a virus produced only a local effect, while a larger dose killed the animal, and the small dose might protect the animal from the fatal effect of a subsequent large dose. Although it is as yet impossible to measure predisposition, and thus to decide the dose for any individual, nevertheless the knowledge of the relation between these two factors is of the utmost importance as throwing light on the mode of spread of epidemics; while the fact that a considerable quantity of the virus is in many cases necessary for the production of a disease explains many anomalies, and affords indications for preventive measures.

Drinking-Water.—A good deal of work has been done during the year on the relation of bacteria to drinking-water. Dr. Percy Frankland brought a number of facts before the Royal Society in June, which showed that the ordinary saprophytic organisms which are found in water multiply with great rapidity when the water is kept for two or three days at about 20° C., even although it contains the merest trace of organic matter. After three or four weeks, however, the greater number have died, and only a few are found. The case is quite different with pathogenic organisms, of which Dr. Frankland tested three forms: bacillus pyocyaneus, Finkler's comma bacillus, and Koch's cholera bacillus. Water from various sources (distilled water, deep-well water, and filtered Thames water) was inoculated from cultivations of these organisms, and then set aside and tested from time to time by means of plate cultivations. The cholera bacilli in most cases died out within twenty-four hours, except when very actively growing forms from broth were used, in which case the bacilli increased slightly in number for a few days. In sewage they grew vigorously, and were found alive even after thirty days. Finkler's bacilli seem to die very quickly in water, and could not be found after twenty-four hours. Elaborate investigations have also been made on the relation of bacteria to water by Meade, Bolton and by Herræus. Bolton also found that while certain of the saprophytic bacteria ordinarily present in water multiplied enormously when the water was kept at a suitable temperature, pathogenic bacteria quickly diminished in numbers under the same conditions, and soon died out. And apparently, with few exceptions, the quality of the water is indifferent. The typhoid bacilli, especially, die rapidly, though in one instance Herræus found considerable multiplication at the bottom of the flask.

MEDICINE.

Diabetes.—Gastric Diseases.—Obesity.—Chronic Heart Disease.—Whooping cough.—Infantile Convulsions.—Peripheral Neuritis.—Pleural Effusion.

THE difficulty of appraising from year to year the value of the new work done in the department of medicine, strictly so-called, grows increasingly great. As the diagnosis of the physician becomes more precise, the surgeon, the bacteriologist, or the writer on therapeutics claims ever wider and wider range. The abdomen, the thorax, and the cranial cavity are successively invaded by the surgeon, until now we see cases of acute peritonitis, of pulmonary vomica, and of cerebral tumour handed over to his care. All, or nearly all the infective diseases are claimed by the bacteriologist as belonging to his department, and the diseases peculiar to women have long since constituted a special course of study and practice. From all this, it results that, in the compilation of such a Retrospect as that annually published in these pages, the subjects which fall into the department of Medicine are those which are the least well defined, the least understood, and, therefore, those which least lend themselves to the method here adopted. In the short notes which follow, no attempt is made to cover the whole field, but rather to gather a few observations which may serve to indicate the direction in which advance is being made. The chemical changes in disease form one of the departments which has attracted most interest, and in the next paragraph a hint may be found of the kind of work to be anticipated.

Diabetes.—In his Croonian Lectures, Dr. Latham gave prominence to the relationship which exists between certain forms of diabetes and rheumatism; in ordinary diabetes, there is reason to suppose that, owing to functional derangement of the liver, the metabolism of the glucose, which reaches the liver through the portal vein, is imperfectly carried out; in what may be called—for convenience—rheumatic diabetes, Dr. Latham appears to assume an imperfect muscular metabolism leading to the production of glucose, of aldehyde (and para-aldehyde) through the intermediary of lactic acid, or of acetone through the intermediary of oxyisobutyric acid. Patients suffering from rheumatic diabetes suffer from neuralgic pains in the joints and limbs, their urine generally contains an excess of uric acid, and probably either glycollic or lactic acid, and they are benefited by salicylic acid. Dr. Dreschfeld, in his Bradshaw Lecture, and Stokvis at the Wiesbaden Congress, both divided the cases of diabetic coma into two classes: diabetic collapse and toxæmia. In the former class, the loss of consciousness and death is produced by sudden failure of the heart, whether due simply to fatty degeneration or to that combined with exhaustion of the nerve centres, has not been determined. Dr. Dreschfeld tentatively made two subdivisions in the second class; in one, the symptoms resemble alcoholic intoxication, and are, perhaps, produced by alcohol; in the other, the toxic agent is either acetone, aceto-acetic ether, aceto-acetic salts, or oxyisobutyric acid; the characteristic symptoms are at first dyspnœa, vomiting, headache, and either restlessness and excitement or depression, then drowsiness, with more severe dyspnœa, followed by complete coma. Stokvis appeared to be very confident that imperfect elimination by the diseased kidneys was the determining cause; but as to the remoter causes he had less to say, and the view favoured apparently both by Dr. Latham and Dr. Dreschfeld, that the toxæmia is due to imperfect metabolism of albumen, is not only probable in itself, but likely to be of practical use in fixing attention on one of the dangers of an exclusively nitrogenous diet; it is known that the sudden change to such a diet from an ordinary way of living has been quickly followed, in a considerable number of cases, by the development of coma.

Gastric Diseases.—In the diagnosis of diseases of the stomach it has always been necessary to rely very largely on the subjective symptoms, and to this one fact is doubtless largely due the somewhat haphazard treatment commonly adopted. Recently, chiefly in Germany, several physicians have begun to study the conditions of the contents of the stomach at stated intervals after meals in various diseased states. Leube, Talma, and Riegel have been the chief workers in this field, and the last named has published an elaborate paper on the subject; his method is to begin by giving a full mixed meal, and then by emptying the stomach through a syphon at various hours, to ascertain the duration, generally over five or six hours, of digestion. The material thus withdrawn is filtered, and the amount of free hydrochloric or organic acids present in the filtrate, its peptic power, and the degree of acidity are ascertained. Perhaps the most interesting fact as yet observed is that in carcinoma of the stomach, except, perhaps, in the very earliest stage, no trace of free hydrochloric acid is ever found, while its absence under any other conditions appears to be very rare. In ulcer, and in dyspepsia with dilatation of the stomach and hypersecretion, attacks of pain were found to coincide with excessive acidity. The operation of washing out the stomach is in itself not devoid of danger, and its indiscriminate use can only bring it into disrepute, but in this country the method does not yet appear to have attracted the notice which it deserves. It seems to be particularly indicated in cases of dilated stomach with slow digestion. Washing out the stomach, combined with the administration of large enemata, has also led to the most brilliant results in intestinal obstruction, supposed to be due to internal strangulation. Miller, of Berlin, has isolated an immense series of micro-organisms from the contents of the alimentary tract; among them were five which, in the course of their development, gave rise to considerable quantities of gas; the amount of hydrochloric acid present in ordinary healthy gastric juice was enough to prevent their development, but, if swallowed with a meal, they had an opportunity of developing, at any rate for some time; by experimenting on himself, he succeeded in producing great flatulent distension, followed by diarrhœa. The existence of these micro-organisms may serve to explain the occasional attacks of flatulent colic and diarrhœa, from which the healthiest persons are liable to suffer, but it is questionable whether they can have much concern in producing, as has been supposed by some writers, the flatulent distension of ordinary chronic dyspepsia.

Obesity.—There is often a good deal of unnecessary hesitation in speaking of excessive fatness as a diseased condition; no doubt a very wide latitude for individual variations and idiosyncrasies must be allowed, but it is not uncommon to find even young adults whose natural functions are seriously interfered with by an extreme fatness. The good results claimed for systems of treatment based on very conflicting theories have been very puzzling, and have, in the eyes of many, given to any attempt to treat the condition on fixed principles an air of charlatanism. But M. Albert Robin has made a contribution to the subject, which appears to possess considerable value; obesity may be due either to excessive assimilation or defective disintegration; M. Robin's point is, that in the former condition the quantity of the urea is increased, in the latter it is diminished; to ascertain whether the urea is increased, it must be compared with the total urinary solids, and to express this relation he has invented the term co-efficient of oxidation; where the co-efficient is increased there is over-assimilation, where diminished, imperfect disintegration. He confirmed the statement of previous observers that an increase in the amount of urea without a corresponding increase in the total urinary solids, followed the imbibition of large quantities of water. Hence, in the class of fat people in whom disintegration is imperfect, he advises copious draughts, while in the other class in whom assimilation is too easy, he cuts down the quantity of fluid. His statements were rather severely criticised in Paris, but on the whole they stood the test well; at any rate, his method rests upon a rational basis of experiment, and seems a great advance on the crude systems now so fashionable in Germany, which seems to consist in little more than a rule of thumb diminution in the quantity of fluids, or a periodical resort to some *bad* where the water contains small quantities of sulphates or chlorides.

Chronic Heart Disease.—Chiefly through the advocacy of Oertel, the system of treating the chronic valvular diseases of the heart by regulated, but rather severe, exercise has been steadily gaining ground. The late Dr. Stokes, of Dublin, had, indeed, long ago written in the same sense; but his teaching was not much heeded, and the tendency has hitherto been to look upon valvular lesion as a disabling condition, debarring the patient from a life of active physical exertion. Many of the statements made in the ordinary text-books and manuals as to prognosis are undoubtedly too gloomy; an admirable paper by Sir Dyce Duckworth, published last summer in this JOURNAL, drew attention to this aspect of the subject; and the discussion at Brighton, initiated by Sir Andrew Clark, and continued by Professor Gairdner, Dr. Clifford Allbutt, Dr. Bristowe, and other experienced physicians, showed how widely-spread was the impression that errors in prognosis were commonly made. Oertel and his followers, however, go much further in that they not only do not forbid active exercise, but actually recommend it as a means of treatment; it is claimed for it that it acts beneficially on the general nutrition, on the nutrition of the heart itself, and, by unloading the venous system (through the perspiration induced), on its functional activity.

Whooping Cough.—The theory that in whooping cough the primary lesion is an affection of the naso-pharynx, appears to be gaining ground. Michael of Hamburg has described brilliant results from the use of powdered benzoin blown into the nose, while Dr. Barlow of Manchester, and Dr. Guelmi of Pavia, have had equal success by painting the pharynx with a 1 per cent. solution of resorcine, as recommended by Professor Moncorvo. The sputum ejected after a characteristic fit of coughing is said to contain minute white or whitish-yellow spots, which, when examined microscopically, are found to consist of micrococci in chains. The use of local applications appears to be founded upon the theory that the micrococci are the determining cause of the disease; the success of the method would at least invite an extensive trial of it, even on empirical grounds.

Intubation of the Larynx.—The extremely unsatisfactory results of tracheotomy in diphtheria have often been attributed to the fact that the operation is generally deferred until the last moment, when the patient is on the verge of total asphyxia. The disease has been for many years extremely prevalent in the Northern States of America, and among the large number of suggestions as to treatment due to American physicians, special mention ought to be made of intubation of the larynx, originally suggested by Loiseau and Bouchut, but first reduced to a working system by Dr. O'Dwyer. The introduction of the tube does not, it is said, present any special difficulty after a little practice. It is made of india-rubber, flattened from side to side, except for a short space in the middle, where it is made circular, in order that it may be less easily expelled during coughing; the length necessarily depends on the size of the larynx, and it should be just long enough to extend from the level of the epiglottis through the rima glottidis, and to within half an inch of the bifurcation of the trachea. The chief objection to its use seems to be the difficulty in swallowing fluids, due to the interference with the action of the epiglottis which the upper end of the tube inevitably causes, and the comparative frequency with which it is expelled by cough; it would appear, however, that the latter objection can be obviated by the choice of an accurately fitting tube. It is claimed for the method that the results are more satisfactory than after tracheotomy; but the cases reported are not as yet sufficiently numerous to give a statistical statement any great weight.

Infantile Convulsions.—The greatest obscurity reigns in the domain of medicine which embraces the so-called functional nervous diseases of infancy, and we must therefore be grateful to Dr. Hughlings Jackson for the ray of light which he has thrown upon the mode in which infantile convulsions are produced. He has applied his well-known synthetical method to the construction of a theory which will serve to explain many of the observed phenomena; he conceives of the central nervous system as containing groups of sensori-motor centres, grouped in three tiers; roughly speaking, the anatomical distribution coincides with this conception, the lowest centres being limited above by the pons, the middle consisting of the motor and sensory cortical centres, commonly so-called, and the uppermost of the brain in front of these motor centres. All the parts of the body are represented in each tier, but the combinations between centres become increasingly complex from the lowest to the highest. Further, it is apparently to be understood that the upper exercises a certain control or dominion over the next lower. In early infancy, the uppermost and middle tiers have not yet been developed, while the lowest is rapidly developing, and is, therefore, in a condition of unstable equilibrium, and, in consequence, liable to respond unduly and irregularly to physiological stimuli when these are intensified. Dr. Jackson goes back to imperfect respiration as the ordinary ultimate cause of convulsions in infancy. The imperfect respiration entails an unduly venous condition of the blood circulating in the respiratory centre, and any slight circumstance leading to a temporary increase in the venosity will produce a stimulus so intense, that, in the imperfectly developed and controlled lower centres it leads to an outburst of irregular activity, that is to say, to asphyxial convulsions. Some recent experiments by Rosenbach tend in the same direction. He has been able to produce fits, which he considers to be of the true epileptic type, by prolonged and forcible stimulation of

the cortex in the dog, whereas stimulation of regions below the cortex, if means were taken to prevent diffusion to the cortical centres, produced convulsive movements which were not of the epileptic type.

Peripheral Neuritis.—The pathology and symptoms of peripheral neuritis have continued to attract a good deal of attention during the year, but as the two interesting papers by Drs. Ross and Buzzard will very shortly be published in these pages, it is not necessary to go over the ground which they so completely covered at Brighton. Attention may also be directed to an elaborate paper by MM. Pitres and Vaillard, published in the *Revue de Medecine*, in which the occurrence of neuritis in locomotor ataxy is specially dealt with, and is shown to be capable of explaining some of the symptoms.

Pleural Effusion.—A discussion on the operative treatment of pleural exudations, which took place during the Medical Congress at Wiesbaden, did not add much to current knowledge; Franzel, who introduced the subject, advised a delay of three weeks, even in serous pleurisy, before tapping, and that even at the end of that time, only a part of the fluid should be withdrawn. Litten and Weber, on the other hand, advised early tapping; Weber and Fiedler laid stress on allowing as much fluid to drain away through a syphon as would flow spontaneously, but Heusner had found that even so dangerous symptoms might ensue. Each speaker preferred a different form of instrument, and the only point upon which there was an approach to unanimity was as to the advantages of resection of ribs in empyema.

SURGERY.

Pasteur's Prophylactic.—Head Surgery.—Chest Surgery.—Laryngectomy.—Operative Treatment of Goître.—Abdominal Surgery.

A REVIEW of the surgical records of 1886 shows that a steady advance has been made in several departments, but especially in that of the operative treatment of injury and disease of internal organs, with a view to attaining not merely temporary relief, but a radical and permanent cure, and the saving of life. The work that has been done in this direction, especially with regard to abdominal and pelvic lesions, has on the whole been attended by brilliant results. Surgical intervention in cases of severe and advanced disease of the thoracic organs—such, for instance, as aortic aneurysm and large pulmonary cavities—has certainly not been very successful, but, on the other hand, the direct operative treatment of affections of the liver and gall-bladder, of penetrating wounds of the abdomen, of intra-peritoneal rupture of the bladder, and of enormous vesical calculi, has had such results as should lead surgeons to reject for the present all ideas as to the finality of their art.

Pasteur's Prophylactic.—This subject, which was fully discussed in a report by Dr. Vignal, published in April in the BRITISH MEDICAL JOURNAL, has hitherto presented rather pathological than surgical interest. The results of Professor Pasteur's investigations and new method have to be tested by time and much study and experience, but at the present date the evidence seems to favour the view expressed by Dr. Hime at the Pathological Society, that a true prophylactic treatment has been established against rabies.

Head Surgery.—In a review of the most important of recent contributions to surgery, Mr. Victor Horsley's paper on Brain Surgery, read at the annual meeting of the Association, claims a prominent place, on account both of its scientific interest and of the novelty of the subject. The great value of this paper mainly consists, in the first place, in a detailed description of the author's method of operating on the brain and his application of antiseptic principles with a view to overcoming the difficulties and dangers of such procedure, and, secondly, in a report of three cases of serious cerebral lesion treated, as was proved by the presence of the patient in each instance, with complete success. In two of these cases the skull had been trephined for traumatic epilepsy, and in the third a tumour of tubercular nature had been removed from its previously ascertained situation at the junction of the lower and middle thirds of the ascending frontal and parietal convolutions. A point of special interest in this record is the great, and, indeed, indispensable aid that is afforded by the results of physiological research in the diagnosis and treatment of coarse and circumscribed lesions of the brain. That trephining, in cases of traumatic epilepsy, is a justifiable, and very often a most satisfactory method of treatment, has been proved by the cases of Mr. Horsley, Dr. Clark, of Glasgow, and other surgeons; but concerning the true value of operative interference in cases of cerebral tumour much, we think, has yet to be learnt. Up to the present time we have had four cases recorded, the well known case of Dr. Bennett and Mr. Godlee, the success of which might be regarded as doubtful; Mr. Horsley's case; one of removal of a soft diffused glioma by Dr. Hirschfelder, of San Francisco, which proved fatal on the seventh day; and a very successful case of endo-cranial, though not cerebral tumour, removed from the base of the skull by Dr. Durante, of Rome. The prospects of cerebral surgery with regard to the removal of new growths do not appear very bright to pathologists. Dr. Goodhart and Dr. Hale White, who have both studied extensive series of cerebral tumours, seem to have good grounds for doubt as to whether any but a small proportion of such growths can be accessible to surgical attack; and in the report of a Special Committee of the Pathological Society on forty-four specimens of intra-cranial growth, it is stated that two only of these seemed suitable for removal. On the subject of head-injuries, a lecture of much interest by Wagner, of Königshutte, has lately been published. This surgeon, who has had considerable experience in the treatment of compound fractures of the skull, holds that, in such cases, too much has been made of the dangers of intra-cranial pressure, and too little of the risk attending septic infection of the seat of injury. He would not apply the trephine for rupture of the middle meningeal artery, except in the presence of symptoms indicating that the hæmorrhage had been very profuse; and he holds that it is unnecessary to interfere with small depressed fractures, with the view merely of preventing compression. On the other hand, trephining, under strict antiseptic conditions, is strongly advocated by Wagner whenever there is reason to believe that foreign matter, however small it may be, has penetrated through the fracture into the cranial cavity. Another lecture of interest dealing with the treatment of cranial lesion has been published in the course of the year by Könlein, of Zurich, who is an advocate of trephining in cases of bleeding from the middle meningeal artery without fracture of the skull. In this report, the author, who has carefully studied the questions of the diagnosis of intra-cranial hæmatoma, and the proper place for the application of the trephine in the operative treatment of the lesion, reports four cases, in each of which the diagnosis of rupture of the middle meningeal artery was confirmed, and an intra-cranial hæmatoma exposed at the seat of operation. On the treatment of bullet-wound of the brain, a suggestive paper, based on a successful case of double trephining, was published early in the year by Dr. Führer, of New York, who, in a case of deeply penetrating wound without serious symptoms of hæmorrhage or compression, would explore the track of the bullet by careful probing, and trephine at the point where the bullet, after having traversed the intra-cranial cavity, has struck the interior of the skull. Other interesting cases of penetrating gunshot-wounds of the head have been reported during the year by Mr. Atkinson, of Leeds; Dr. Macdonald, of New York; and Mr. Astley Bloxam.

Chest Surgery.—Of the few contributions made during 1886 on the subject of chest surgery, that probably of most interest is the paper read before the Royal Medical and Chirurgical Society, in March, by Dr. C. Theodore Williams and Mr. Godlee, on the operative treatment of bronchiectasis. Two cases of this condition were reported in which paracentesis had been performed, on one patient with good results, on the second with but moderate success. The operation is here held to be indicated when the bronchiectasis is confined to one lung, is situated in the lower lobe, and has, overlying it, an adherent pleura. The discussion of this paper indicated—as will very probably be confirmed by any future cases of a like kind—that the value of operative treatment of such morbid conditions of the lung is likely to be seriously compromised by difficulty in diagnosis and the danger of hæmorrhage. With regard to the surgical treatment of empyema, Dr. Lagrange, of Bordeaux, has lately directed attention to the risk, in operations on the thorax for this disease, of wounding the diaphragm, and, with a view to the prevention of so serious an accident, insists on the necessity of never making the incision in the wall of the chest below the sixth rib. Operative interference in cases of hydatid disease of the lung has been advocated by Israel, of Berlin, who holds that an opening into the pleural cavity constitutes no danger to life, provided it be made under antiseptic precautions, and be speedily closed, the admitted air, it is stated, being soon absorbed. Notwithstanding the opinion held by this surgeon, that the risk of a radical operation is smaller than that of simple puncture of the cysts in cases of hydatids of the lung, the procedure recommended by him, involving as it does extensive resection of one or more ribs, and free section of the costal pleura, is of too heroic a character to meet with wide and serious attention.

Laryngectomy.—Extirpation of the larynx, an operation that for some few years has been of frequent occurrence in the practice of Billroth, Thiersch, and Hahn, has during 1886 been performed in Paris by Péan in two cases, one of which proved successful, and by Labbé in one case, in which death occurred from pneumonia after an interval of four months. The operation has in this country been recently

practised by Sir Wm. MacCormac, and at a meeting of the Clinical Society on November 9th a discussion was held on cases reported by Dr. Semon, Mr. Morris, and Mr. Butlin. The procedure of total removal of the larynx is well described by Mr. Pick as a "terrible one," and even if not speedily fatal, seems to offer but poor prospect of prolonged freedom from relapse. In Mr. Butlin's opinion "complete excision for carcinoma should be practised only in very rare instances, as the mortality due to the operation is large, the prospect of complete cure very small, and the patient might be less comfortable after than before the operation." Partial or unilateral excision, though less severe, and not so fatal, is applicable but to a few selected cases, and as a means of affording relief from dyspnœa and suffering seems in a large proportion of cases to present no advantage over inferior tracheotomy.

Operative Treatment of Goître.—At the annual meeting at Brighton, Sir William Stokes reported to the Section of Surgery an instance of the frequently observed dependence of a condition of myxœdema on complete removal of the thyroid gland, which was first fully described by Kocher, and which has since been carefully investigated by Mr. Horsley. In consequence of the frequent occurrence of the so-called cachexia strumipriva after complete thyroidectomy, and of the views based on the results of Mr. Horsley's experiments, the operation has naturally lost favour, and, indeed, in some quarters, is now regarded as an unjustifiable proceeding, its place being taken by less radical measures, such as partial excision, removal of diseased tissue by the process of "shelling-out," and simple division of the isthmus.

Abdominal Surgery.—In reviewing the additions made during the year to the extensive subject of abdominal surgery, it is barely possible to do more than refer briefly to some of the more important contributions that have been made chiefly by British, American, and German surgeons. On the question of the value of laparotomy in the treatment of perforative and persistent peritonitis, an interesting paper has been published by Krönlein, who, though acknowledging the unfavourable conditions under which such treatment is applied, as, for instance, the collapsed state of the patient, the difficulty in establishing a sure diagnosis, the complex arrangement of the abdominal organs, the adhesion and distension of coils of intestine, and the probable difficulty in finding the perforation, is still in favour of the operation, as affording the only opportunity of rescue from death. Three cases are reported, of which two were fatal, and one, in the words of the author, was attended with the most splendid results. Mikuliez, who is also in favour of this treatment, has contributed to Volkmann's collection a lecture on laparotomy in cases of gastric and intestinal perforation, and has reported three cases, of which one proved successful. Strudenski, a Russian surgeon, has reported one case of purulent peritonitis treated with good results by laparotomy; and Naumann, a Swedish surgeon, four cases of tubercular phthisis, in two of which the operation was followed by death. In New York, Dr. Hall has operated successfully in a case of suppurative peritonitis, due to perforation of the vermiform process. At home, Mr. Barker has reported to the Clinical Society a case of successful operation for the relief of acute intestinal obstruction associated with acute general peritonitis. To the subject of the treatment of gunshot and other penetrating wounds of the abdomen, for which so much had been done by Marion Sims, Parkes of Chicago, and Bull of New York, another contribution has been made in the United States by Professor Dennis. In the treatment of deep stabs and of gunshot wounds involving the abdominal cavity, Professor Dennis, bearing in mind the difficulty of diagnosing the extent of the injury, and the inevitably fatal result of leaving to itself any perforation of the intestinal tract, and holding that laparotomy performed with strict antiseptic precautions is not a serious operation, would advocate this procedure in doubtful cases as a diagnostic measure, and for the purpose of exploring thoroughly the contents of the abdominal cavity. At the annual meeting of the American Medical Association, held at St. Louis in May, Dr. Senn, the president of the Surgical Section, held that exploratory laparotomy was justifiable in all doubtful cases, for the arrest of hæmorrhage, the removal of extravasation, or the restoration of a breach of continuity. With regard to exploratory laparotomy in cases of gunshot of the abdomen, Dr. Packard of Philadelphia, has made some suggestions which claim serious consideration. It is pointed out that "the procedure is in itself of great gravity, and the patient's general condition must be fairly good to enable him to withstand this additional shock." The surgeon is advised not to carry out such treatment on his sole responsibility; for though "his main object must be to do all that is possible to save life; he must not overlook the fact that his course may be severely criticised, especially in cases which give rise to medico-legal inquiry." The chief contributions relating to operations on the stomach that have been published during the year are, one by Credé, of Dresden, on the Extraction of Foreign Bodies from the Stomach (*Archiv für Klinische Chirurgie*); a report of a successful case of Gastro-enterostomy for Cancer of the Stomach and Pylorus, by Mr. Barker; another case by Mr. Morse (BRITISH MEDICAL JOURNAL, Vol. i, 488), and a case of Jejunostomy for Cancer of the Pylorus, by Mr. Golding Bird (Clinical Society's *Transactions*). In April, Mr. J. Knowsley Thornton reported to the Royal Medical and Chirurgical Society two cases of splenectomy, one of which was successful, and appended an analysis of all previously recorded cases that he had been able to find. Ceci, of Genoa, has also lately put on record a case in which he removed, with good result, a hypertrophied and displaced spleen from a young subject. To the scanty literature on the surgery of the pancreas a very elaborate and able contribution has lately been made by Dr. N. Senn (*International Journal of the Medical Sciences*). Partial excision of this organ, it is stated, whether for injury or disease, is a feasible and justifiable surgical procedure. Partial excision of the splenic portion is indicated in cases of circumscribed abscess and of malignant tumour, in which the disease can be completely removed without danger of compromising pancreatic digestion or inflicting injury upon adjacent organs. Dr. Senn has proved by experiments on animals that extravasation of fresh and normal pancreatic juice into the peritoneal cavity is removed by absorption without causing peritonitis. Billroth has performed partial excision of the spleen in two cases, and an instance has recently been reported by Sulzer of removal, with a fatal result, of a large pancreatic cyst, which was supposed to be ovarian. The meetings of the surgical section at the Annual Meeting were this year rendered especially interesting, not only by the paper on brain-surgery, but also by several valuable papers, and a discussion on the surgery of the liver. The series of papers was headed by some remarks by Dr. George Harley on hepatic phlebotomy, and consisted in contributions from Mr. Thornton, Mr. Willett, Mr. Howard Marsh, and Mr. Lawson Tait on cholecystotomy and the treatment of abscess and hydatid cyst of the liver. The term "hepatic phlebotomy" is applied by Dr. Harley to a procedure which consists in the insertion into the upper and convex portion of the liver of a long trocar for the purpose of drawing off blood directly from the organ, and thus relieving any engorged condition. Like others who have had much experience of chronic and tropical affections of the liver, Dr. Harley has found much benefit to be derived from puncturing the liver's capsule, as a remedial measure, in cases of chronic congestive hypertrophy. The paper read by Mr. Knowsley Thornton shows what good may be done by operative surgery under antiseptic conditions in cases of hepatic abscess, hydatid cyst, and accumulation of gall-stones. Among the many interesting contributions in this series of papers on liver surgery, we have to notice a report from Mr. Lawson Tait, of thirty cases of cholecystotomy performed for the removal or crushing of gall-stones, for suppurating or distended gall-bladder, and for cholæmia. This list, which includes but one fatal case, establishes beyond dispute, Mr. Tait holds, that that operation, when properly performed, is as devoid of risk as any surgical proceeding possibly can be. In June, Professor Poulet, of Paris, published a case in which he had treated a hydatid cyst on the anterior surface of the liver by performing abdominal section; and, after removal of the fluid contents, and excision of the free portions of the cyst-wall, by stitching the edges of the hepatic cavity to the wound in the abdominal wall, in order to establish a fistula. Poulet, in his paper (*Revue de Chirurgie*), has given an analysis of thirty-nine collected reports of hydatid disease of the liver treated by abdominal section, and pointed out the indications for surgical interference in such instances, and the modifications adapted to the varying situations of the cyst with regard to the liver in different cases. Another French surgeon, Dr. Paul Reclus, has also recorded a successful case of free abdominal incision in the treatment of hydatid cyst of the liver, and has stated that in his opinion the application of caustics with subsequent opening of the cyst by knife or trocar is certainly not less dangerous than a free incision into the peritoneal cavity. In Russia, where surgeons have much experience of hydatid disease, free surgical treatment is now much in favour. Korach has practised incision in eighteen cases, and Sklifassovsky, of Moscow, has, in three cases, successfully practised free incision and sewing of the wall of the cyst to the edges of the abdominal wound.

Renal Surgery.—But little, if any, further advance has been made this year in renal surgery. The indications for and against removal of the kidneys have perhaps been more carefully studied, and there seems to have been a tendency to restrict, rather than to widen, the range of the operation. Dr. P. Wagner, of Leipzig, who has written an elaborate paper on surgical diseases of the kidney, based on cases under the care of Professor Thiersch, seems to be much impressed with

the probabilities of the danger of removing a single organ, or of leaving an organ incapable, through disease or atrophy, of performing its full function. The posterior and extra-peritoneal method of nephrectomy is still preferred by a large majority of surgeons, and in cases of large renal tumour, König, in order to avoid wounding the peritoneum, would perform a complicated extra-peritoneal section, by which the muscles of the abdominal wall are freely divided, and are consequently liable to be much weakened. Among the most important of the few recent contributions on nephrectomy is one by Von Bergmann, who is an advocate for the operation which he has performed in eleven cases either by straight or oblique posterior incision.

Suprapubic Cystotomy.—The subject of suprapubic cystotomy for removal of stone has, during the year, been fully discussed by Sir Henry Thompson, at the annual meeting of the Association; by Mr. Cadge, in his course of Hunterian Lectures at the College of Surgeons (BRITISH MEDICAL JOURNAL, Vol. i, 1149, 1202.); and by Mr. Barwell and others, at the Royal Medical and Chirurgical Society. The operation has now been frequently performed, both at home and abroad, and, on the whole, with most satisfying results. There can be no doubt that the modern method of cystotomy is of great value in the removal of very large stones, as in the cases that have been reported by Mr. Rivington, Mr. Thomas Smith, and Dr. Morison, of Hartlepool. According to Sir Henry Thompson, "suprapubic lithotomy will prove a safer and far easier operation, in the hands of most surgeons, than lithotrity for hard stones when these have arrived at a weight of about 1½ to 2 ounces"; but whether in such cases the high operation should always be preferred to perineal lithotomy must, we think, still remain open to doubt. The efficacy of rectal distension in cystotomy above the pubes, on which so much stress is laid by the advocates of this operation, is questioned by Mr. Barwell, who has been led by a series of experiments to form the opinion that this distension makes but very little difference in the position of the peritoneal fold in front of the bladder. That there is a risk of wounding the peritoneum in the high operation has been proved by a case reported by Polaillon, of Paris; and certainly, when the urine is foul and decomposed, there is danger of cellulitis. In the opinion of König, suprapubic cystotomy is a less difficult procedure than the perineal operation, but is attended with certain serious risks, especially septic inflammation of the anterior abdominal wall. With regard to the operative treatment of tumours of the bladder, there seems to be less room for doubt as to the superiority of the high method. On the subject of vesical morbid growths, valuable contributions have been made by Küster (Volkmann's *Sammlung*), Sir H. Thompson, and Guyon, of Paris. The BRITISH MEDICAL JOURNAL of June 19th and October 16th contains records of instances of cystotomy for tumours by Mr. Greig Smith and Mr. Southam. The long record of invariably fatal cases of intra-peritoneal rupture of the bladder has at last been followed by two recent instances, under the care of Sir Wm. Mac Cormac, of successful treatment of this very serious injury by abdominal section and suture of the wound in the bladder.

Surgery of the Vascular System.—With regard to the surgery of the vascular system, the following papers of importance are to be found in the last volume of the *Medico-Chirurgical Transactions*: A record by Dr. W. Cayley of a case of thoracic aneurysm treated by the introduction of steel wire; an experimental inquiry on the ligation of large arteries in their continuity, by Mr. C. A. Ballance and Mr. W. Edmunds; and a contribution from Mr. Rivington on the subject of wounds of blood-vessels by foreign bodies. Before the Clinical Society, a paper of much practical value was read, in May, by Mr. R. W. Parker on the structure and treatment of nævus. Another case of aortic aneurysm treated by the introduction of wire, with the usual unsatisfactory result, was reported early in the year by Dr. Ransokoff, of the United States. On March 29th, Mr. Bennett May tied the innominate artery for aneurysm, but with a fatal result from secondary hæmorrhage on the nineteenth day. The occasional occurrence of venous thrombosis and embolism after simple fracture has during the year been pointed out by Bruns, of Tübingen, who has collected thirty-five cases of this grave complication. At the last meeting of the German Society of Surgery, a paper of some importance on the treatment of arterio-venous aneurysm was read by Dr. Bramann, of Berlin.

Fracture of the Patella.—Most of the contributions of importance relating to injury of bone deal with fracture of the patella. The treatment of simple transverse fracture of this bone by exposure and suture has been warmly supported by Dennis of New York, and opposed by Brunner of Zurich, who holds that the results hitherto obtained by this method are not such as to justify its practice. Mr. Treves, of the London Hospital, has written on treatment of this fracture by Malgaigne's hooks (BRITISH MEDICAL JOURNAL); and on March 18th Mr. G. R. Turner read, at the Harveian Society, an able paper on compound fracture of the patella, containing a record of a case under his own care, and an analysis of nineteen other instances.

Fistula in Ano: Radical Cure of Hernia.—Among the few recent contributions of importance bearing strictly on the surgery of the intestinal canal, reference may be made to a paper (*Medical Record*) by Dr. Stephen Smith, of New York, on the immediate closure and rapid cure of fistula *in ano*; to a description, by Dr. McEwen, of a new operation for the radical cure of oblique inguinal hernia (*Annals of Surgery*); and to a clinical study by Anderegg, of Bâle, of 136 cases in which radical cure of hernia had been attempted by operative measures (*Deutsche Zeitschrift für Chirurgie*).

PHARMACOLOGY AND THERAPEUTICS.

Lanoline.—Pure Terebene.—Urethan and Hypnone.—Strophanthus Hispidus.—Benzol-eupnoin.—Binoxide of Manganese.—Digestive Ferments.—The Section of Pharmacology and Therapeutics at the Annual Meeting.—Collective Investigation Committee.

Liebreich's Lanoline.—The year 1886 has been characterised by considerable activity in the field of pharmacology and therapeutics. One of the first important papers to attract attention was a communication from Professor Oscar Liebreich, the distinguished Professor of Materia Medica in the University of Berlin, on a new substance which he has called Lanoline, which he recommends as a basis for ointments, and for other purposes. "Lanoline" is a cholesterin fat, differing from the ordinary fat of the panniculus adiposus chiefly in the fact that it contains crystals of cholesterin in place of glycerine. It is extracted from the fat contained in the wool of sheep, and, in a crude and impure form, has long been known as "wool-oil." Cholesterin fats have the great advantage of not being decomposed by boiling with alkaline solutions, whilst glycerine fats are at once split up into glycerine and soap. Pure lanoline absorbs water with the greatest facility, and can be rubbed into the skin with ease. From the peculiarity of its composition, it can never become rancid, and is consequently well adapted for the treatment of a great number of local affections. It adheres to the skin, and at the same time exerts a mild and soothing action thereon. It will speedily overcome, as Dr. Shoemaker has shown, rough and irritable conditions of the integument, and is probably the best application for chaps, chronic eczema, psoriasis, and allied affections. Its introduction as a therapeutic agent attracted much attention, and it is now largely employed in place of vaseline and other less absorbable fats, both alone and in combination with other substances.

Pure Terebene.—In the early part of the year there was much discussion as to the value of pure terebene, and its ally, turpene, especially in the treatment of chronic bronchitis and winter cough. Pure terebene has been so largely employed, that its action and mode of use are now thoroughly understood and appreciated. The great difficulty was to obtain the substance pure and free from other products of distillation; but this has at last been overcome, and there is now less fear of irritating and dangerous products being prescribed or dispensed. Turpene is a true hydrate of turpentine, or turpentine camphor. It is administered internally, in doses of from four to ten grains, usually in the form of compressed tabloids. It is a good expectorant, and sedative to the bronchial mucous membrane, and, in cases of chronic cough, gives excellent results. It has also been recommended as a diuretic, and has considerable power in increasing the flow of urine.

Urethan and Hypnone.—Urethan and hypnone, the two new hypnotics, have also been extensively used, although there is still some diversity of opinion as to their value. For the introduction of the first of these we are indebted to Schmiedeberg, of Strasburg, who fully investigated its action on the lower animals. Dr. Myrtle, of Harrogate, contributed some valuable and interesting observations on its use in various forms of insomnia. It should be given in doses of from one to five grains, and its effects are usually speedy and satisfactory; there being no subsequent constipation or headache. Hypnone is a liquid, and is best given in soluble capsules. The observations of Dr. Dujardin-Beaumetz on this new remedy have been confirmed by Constantin Paul and Huchard. The hydrobromate of hyoscine has been given as a hypnotic in doses of one-hundredth of a grain.

Strophanthus Hispidus.—Since the publication of Professor Fraser's article on strophanthus hispidus, numerous trials have been made of this new cardiac remedy, and there seems every probability that ere long it will entirely supersede digitalis. Dr. Lindsay Proteus

has published notes of several cases in which its exhibition was attended with prompt relief of palpitation, irregularity of the heart's action, and other distressing symptoms. Both for its cardiac action and as a diuretic, it is probably more efficient than any other remedy with which we are acquainted. In cases of functional cardiac irregularity, unattended with lesions of the valves, it may be regarded almost as a specific. In dropsy, whether of cardiac or renal origin, it speedily increases the urinary flow, and lessens the œdema. The tincture is the best preparation procurable, and the dose should not exceed five minims three times a day, to begin with. There are many varieties of strophanthus, and care should be taken to collect only the species referred to by Professor Fraser in his paper. It is not safe to substitute tinctures made from other species of strophanthus, the physiological action of which may not have been determined.

Benzol-ecgonin.—Dr. Ralph Stockman's article on the action of benzol-ecgonin, although chiefly of scientific interest, has its practical bearings. His conclusions may be summed up briefly by saying that he finds that this new substance is practically identical with caffeine in action, there being, however, minor points of difference.

Binoxide of Manganese.—Binoxide of manganese is being largely employed as an emmenagogue. Its introduction for this purpose is not new, as it was tried with good results about three or four years ago. If not quite as certain as permanganate of potassium, it has some advantages over that salt, the chief being that it possesses no caustic or irritating properties, and that it can be administered at any time, irrespective of food. The permanganate is apt to cause irritation of the mucous membrane of the stomach and œsophagus, unless given immediately after meals and with copious draughts of water. Both drugs act in the same way, and may be regarded as prompt and certain emmenagogues.

Digestive Ferments.—Several papers have appeared on digestive ferments, and it is now generally recognised that if any benefit is to be derived from the administration either of pepsine or extract of malt, experiments must be previously undertaken to ascertain their purity and activity. The dose of pepsine usually administered is too small to exert any very decided effect on the contents of the stomach, whilst extract of malt is not uncommonly prepared at a temperature which effectually destroys the ferment on the presence of which its activity depends.

Section of Pharmacology and Therapeutics at the Annual Meeting.—The work of the Section of Pharmacology and Therapeutics at the Annual Meeting at Brighton was of exceptional value, and was the means of calling attention to many new remedial agents. Dr. Lauder Brunton chose as the subject of his address the connection between chemical constitution and physiological action.

Collective Investigation Committee.—During the greater part of the year, the Collective Investigation Committee of the British Medical Association has extended its sphere of action, and has undertaken a series of therapeutical inquiries into the value of certain new remedies. The first memorandum issued was on the use of hamamelis in arresting hæmorrhage, whilst the second dealt with the value of pure terebene in the treatment of winter cough. The notes issued with these papers are clear and concise, and it is stated that they have been found of much value by medical men in many parts of the country. The inquiry is still open, but the results will shortly be tabulated, and a report issued.

OPHTHALMOLOGY.

The Ophthalmological Society.—Ophthalmological Section at the Annual Meeting.—The Von Graefe Medal.—Cucaine.—Sympathetic Ophthalmitis.—Substitutes for Enucleation.—Refraction.—Myopia.—Cataract Operations.

The Ophthalmological Society.—Although the past year can boast of no discovery comparable to that of cucaine, it has not been unprofitable. Further experience has been gained of the results of novel modes of treatment, and of new methods of diagnosis. The work done by the Ophthalmological Society, and at the Ophthalmological Section at the Annual Meeting of the Association, was fully equal to that of former years. The *Transactions* of the Ophthalmological Society open with a masterly paper by Dr. Hughlings Jackson, on the Connection of Ophthalmology and Diseases of the Nervous System. Mr. Berry's charming little book on *Subjective Symptoms* might with advantage be read in connection with this. The second Bowman lecture, delivered a few weeks ago by Professor von Zehender on Parasitic Diseases of the Eye (British Medical Journal, ii, 1073), dealt in a most able manner with a subject which is, in many respects, a modern one, and which has, perhaps, had more influence upon our views of the pathology of affections of the eye than in any other branch of surgery. The *Transactions* contain besides some reports of especial value, which will be again referred to.

Ophthalmological Section at the Annual Meeting.—Mr. Hutchinson's paper on Choroiditis at the Annual Meeting, illustrated by an immense collection of coloured illustrations of the fundus, forms an unrivalled clinical record. It is much to be regretted that lack of time or of skill has hitherto rendered the collection of such illustrations an impossibility to most; it is to be hoped that the sketch-book recently published by Dr. Haab may, in the future, render this more possible.

The Von Graefe Medal.—Ophthalmologists throughout the world will endorse the verdict of the Heidelberg Ophthalmological Society in awarding the von Graefe Commemoration Medal to Helmholtz, and it would have been impossible to have found a more fitting spokesman than Donders, or words more suitable than those used by him (for full report see British Medical Journal, ii, 1137).

Cucaine.—The hopes that were entertained of the value of this drug have been fully justified; it has proved an efficient anæsthetic for almost all operations on the eye, and but few accidents have followed its use. Some of these, such as desquamation of the corneal epithelium, can be guarded against by keeping the eyelids closed between the installations, while others, there is some reason to think, were not due to the cucaine alone, but to the combined action of it and of corrosive sublimate. The subject of these local lesions will be found discussed in a previous article (British Medical Journal, August 7th, 1886). General toxic symptoms have not, we believe, been recently recorded after its use for ophthalmic purposes, although they have occurred in other circumstances; this is probably due to the fact that the solutions usually employed have been less concentrated than those employed in general surgery.

Sympathetic Ophthalmitis.—The pathology of this affection has long been a matter for discussion, and the prevalent views seem now about to deviate slightly from the road on which they have recently been travelling. At the end of 1885, Deutschmann's theory that the inflammation of the sympathising eye was caused by the passage into it of micro-organisms from the injured eye along the optic nerves and chiasma, if not universally accepted, had certainly more adherents than any other. Although, however, the experimental evidence was very strong, there were several difficulties in the way of its acceptance. It was a matter of some uncertainty what was the normal direction of the lymph-current in the optic nerves; but, in whichever direction it flowed, the theory assumed that in one eye the micro-organisms travelled against it. Some recent experiments of Gifford's (British Medical Journal, ii, 826) have placed the matter in a new light. By the injection of fluid containing coloured substances in very fine suspension, he demonstrated that in each optic nerve there are two currents, the one in the inter-sheath space from the brain to the eye, and the other along the central vessels of the retina, which, leaving the nerve with the vessels, passes to the apex of the orbit. Further experiments on rabbits with the spores of the anthrax bacillus demonstrated that the second eye became affected by their travelling to the brain along this latter route, and that they were then transmitted down both optic nerves. In connection with this branch of ophthalmology should be read the comprehensive report of the committee appointed by the Ophthalmological Society. The evidence adduced is entirely clinical, not pathological, but much of it has a most important bearing upon questions of treatment and prognosis. For the conclusions that may be legitimately deduced from the evidence, we must refer the reader to the report; we will merely allude to the fact that the view generally held in this country, that enucleation has a favourable influence upon the course of the disease in the sympathising eye is, on the whole, supported by the evidence, and that the result of operations performed upon the exciting eye do not appear to be so unfavourable as it has been the fashion of late years to consider.

Substitutes for Enucleation.—As some of these were proposed with the view of diminishing the risk of meningitis that occasionally follows the removal of the eye, this seems a fitting place to refer to a most valuable paper by Mr. Nettleship (*Transactions of the Ophthalmological Society*) upon this affection. The discussion which followed its reading showed how widely the treatment of suppurating eyeballs differs in this country, some surgeons enucleating such eyes without hesitation, while others never do so, even when the inflammation has subsided, but allow the patient to wear an artificial eye over the shrunken stump. Evisceration, or emptying of the sclerotic, and Mules's operation, of introducing a glass sphere into the cavity, have not, we believe, been very widely adopted, but a considerable number of operations must now have been performed without any

untoward result having, so far, occurred. At the Brighton meeting, Mr. Adams Frost proposed to modify the operation by enucleating the globe, and then introducing Mules's sphere into Tenon's capsule, uniting this and the muscles over it. Until results have been published, it is impossible to estimate the practical value of this operation. At the same meeting, an attempt was made by Dr. Bell Taylor to re-introduce resection of the optic nerve as a substitute for enucleation. The operation may, however, be said to have had a fair trial, and to have been definitively abandoned by most surgeons.

Refraction.—Although the past year can boast of the introduction of no new test for refraction, or any discovery as to the causes of ametropia, it will be remembered as having seen the appearance of the best book on refraction since Donders' great work. The English translation of Landolt (*On Refraction and Accommodation*) will probably for many years be the standard book upon the subject; we have reviewed it in detail (BRITISH MEDICAL JOURNAL, vol. ii, p. 681), and need only say now that it is admirably adapted to serve either as a book of reference to the practitioner, or a text-book for the student. This year has also seen the commencement of a new edition of Helmholtz's *Physiological Optics*, a book which may be said to be one of the classics of ophthalmology, although, from the large prominence given to the mathematical part of the subject, and from its more theoretical character, its circle of readers will be a limited one. It is to be hoped that a good English translation will soon make its appearance. Loring's book on *Ophthalmology*, of which only the first volume has at present appeared, dealing to a large extent with refraction, as well as with the use of the ophthalmoscope for other purposes, may be mentioned in this connection; its thoroughness and clear style will render it a favourite with English readers, and it will teach much even to those who have long been accustomed to use the ophthalmoscope. This book contrasts favourably with the second edition of Galezowski's *Traité Iconographique d'Ophthalmoscopie*, which, although covering a wider field, treats to a great extent of the same subjects. The history of the ophthalmoscope, and many of its varieties, are well described, but as most of these are obsolete, they have not much interest for the practitioner. But the account of the ophthalmoscopic changes that occur in connection with various general diseases is hardly up to date, and there are few references except to French writers; the coloured illustrations in the atlas, which forms a large part of the book, are exceedingly crude, and we have failed to find any that are in the least degree true to nature. We could wish that Loring had introduced more coloured plates, as the few that are given, although leaving much to be desired, are decidedly above the average of such productions. The shadow-test still holds its own, and is almost universally recognised in this country as the best test for diagnosing the presence of astigmatism and the direction of the principal meridians. It possesses the great advantage over direct ophthalmoscopic examination, for those who only occasionally require to test the refraction, that it is easily learnt, and as it requires no technical skill, it is not soon forgotten. As a modification of the test, for hospital work, we note the apparatus contrived by Mr. Haines (*Ophthal. Rev.*, Oct.) for rapidly changing the lenses. This cannot compare with Mr. Couper's latest optometer, but the cost of the latter will be an obstacle to its general adoption.

Myopia.—The causes and mode of prevention of myopia are subjects which always engage much attention, and this year has been no exception to the rule. The publication of an English translation of Cohn's *Hygiene of the Eye in Schools* will do much to bring before English surgeons the evidence on which many of the theories in reference to myopia rest, but it is much to be hoped that it will serve a still more useful purpose in bringing under the notice of the educational authorities the evils that may result from "overpressure," and the means by which they can be minimised. The Germans have for many years been much greater offenders in this respect than ourselves, and are reaping the fruit in the enormous prevalence of myopia in their country. In the large board-schools, most of the structural defects that were so injurious in the older buildings are avoided, but much remains to be done in the way of instructing teachers as to the capabilities of the growing eye and the mischief that may result from its improper use. There can be no question as to the inconvenience of myopia to the individual, and the injury that would accrue to the nation if its prevalence were much increased, but considerable doubt has been thrown upon the view, hitherto generally held, that all cases of myopia are liable to continue to grow worse after school life, and to develop into the so-called "malignant" form. Certainly many do not get much worse after the termination of scholastic life, and the view has gradually been gaining ground that these cases are essentially different from the progressive form. This view is warmly supported by Landolt. We merely note this tendency; we have no space here to discuss the evidence bearing on the question.

Cataract Operations.—There is not much that is new to record in connection with this subject. The plan of getting rid of the cortex by injecting a stream of water into the capsule, as suggested by Dr. MacKeown, has, we believe, given satisfaction to those who have tried it, but the necessity of arranging several preliminary details, and the uncertainty at the commencement of an operation whether it will be required, much restricts its use. De Wecker, in Paris, uses a syringe, which, to our mind, is much more convenient, and injects a small quantity of an antiseptic fluid kept ready for the purpose. Graefe's operation is still the favourite in this country; in France, on the contrary, the iridectomy is generally omitted, and the incision is usually entirely corneal. The electric light has been found most useful in detecting transparent cortex and in needling operations. We note a tendency in some quarters to return to the ancient custom of not covering the eyes with a pad or giving them any further protection than is afforded by the closed eyelids; we believe that this tendency is a dangerous one, and that the modern practice is based upon sound principles.

OBSTETRICS.

Sänger's Operation.—Pyosalpinx in the Puerpera.—The Alternatives of Craniotomy.

Sänger's Operation.—In a paper read before the British Gynæcological Society, Dr. Meadows advocated the abolition of craniotomy, and the substitution, in its stead, of Sänger's modification of Cæsarean section. No doubt something is to be said on this point, but it is to be questioned if the maternal mortality would be diminished in anything like the proportion estimated by Dr. Meadows. In the practice of some obstetricians, the maternal mortality in craniotomy has been *nil*, and it is not to be supposed that they will readily change such successful results for Sänger's operation with its about 25 per cent. maternal mortality, especially as many cases are on record where live children have been delivered in cases where craniotomy was performed in the first labour. The last word has by no means been said on this point, and it will require much consideration and discussion before anything approaching a final judgment is reached.

Pyosalpinx in the Puerpera.—Dr. Grigg has published the *post mortem* notes of four cases of patients who died in Queen Charlotte's Lying-in Hospital. Dr. Allchin, who made the necropsies, found that death was not due, as might have been supposed if no *post mortem* examination had been made, to septicæmia, but to pyosalpinx on one or other side of the uterus. This is a new and instructive light on some of the causes of puerperal mortality. It is to be hoped that the new work inaugurated by Dr. Grigg will speedily be followed up by other obstetric practitioners. It offers a fruitful field for fresh research. The conclusion arrived at was that two, at least, out of these four patients, perhaps even three, might have been saved by operative interference.

The Alternatives of Craniotomy.—Dr. Robert Barnes, at the meeting of the Association at Brighton, summed up an exhaustive contribution to the subject with the conclusions that the legitimate aspiration and tendency of science is to eliminate craniotomy on the living and viable child. The advance of hygiene, improvements in the forceps, in turning, in the induction of labour, and in obstetrics generally, have materially curtailed the field within which craniotomy can be justifiable. In pelvic contractions, immovable tumours, rupture of the uterus, atresia of the vagina or cervix, some modification of the Cæsarean section was advisable. Dr. Kinkead also read a paper on the same subject, and concluded by saying, if the Cæsarean section was performed before the vital powers were weakened and the uterine tissues injured by protracted parturition, if it were done with the means at our disposal for controlling hæmorrhage, with the continuous suture, with thorough cleansing of the abdominal cavity, with scrupulous cleanliness and care in every stage, he had no doubt that it would be as safe for the mother as craniotomy, and that, considering the very high probability of saving the child, it ought to have a prior place to the only operation sanctioned by surgery which is undertaken with the avowed object of destroying life. Finally, he pointed out that to reduce the bulk of the child, or to extract its mutilated remains through a pelvis of two and a half or less conjugate, was an operation of extreme difficulty, one occupying a very considerable period of time, and needing for its successful accomplishment, as far as the mother was concerned, very great experience, and an amount of manual dexterity hardly to be acquired out of large cities; while, on the other hand, the Cæsarean section was an easy operation, capable of successful performance by any surgeon of ordinary skill.

GYNÆCOLOGY.

Ovariotomy. — Oöphorectomy. — Polymastia. — Foreign Gynæcological Literature.

Ovariotomy.—In May, we published a remarkable original article by Mr. Lawson Tait, on one hundred and thirty-nine consecutive ovariotomies performed in the years 1884 and 1885 without a death. Besides the description of the brilliant results which the author could claim, the paper was important for several other reasons. The practice of flushing out the peritoneum with hot water was strenuously advocated. An open contempt of antiseptic principles was expressed throughout, the author declaring that the fluid employed for the purpose just named was plain unfiltered tap-water, warmed by the addition of enough from the boiler, and full of germs and small beasts of thirty-four different varieties. Mr. Tait further expressed himself in favour of exceedingly limited abdominal incisions. In October, Mr. Knowsley Thornton read a paper at the Royal Medical and Chirurgical Society on "Three Hundred additional Cases of Complete Ovariotomy and Twenty Cases of Exploratory Operation," in which he noted that all these operations had been conducted with full antiseptic precautions, and claimed a progressive decrease in mortality throughout his series. In the discussion which followed, Dr. Playfair observed that he had recently operated on five cases in succession at King's College Hospital without the spray; indeed, on one occasion, when he asked an assistant to prepare it, he was told that there was not a spray-producer in working-order in the hospital. Strict antiseptic precautions, as the term was understood a very few years since, is certainly becoming less and less practised by ovariotomists; yet there do not appear as yet to be sufficient grounds for its complete abolition. It must be remembered that the successful non-antiseptic operators are all surgeons of very large experience, and their triumphs must be chiefly due to their skill.

Oophorectomy.—The question of oöphorectomy and removal of the appendages has been the subject of discussion at the Section of Obstetric Medicine, during the Annual Meeting, when the debate was led by Dr. Thomas Savage, at many meetings of societies, and in the pages of several publications. The October number of the *International Journal of the Medical Sciences* contains a Symposium on Castration in Mental and Nervous Diseases. Sir Spencer Wells, in a vigorous article, spoke in terms of the strongest reprobation against the freedom with which some surgeons resorted to oöphorectomy. That operation, he said, referring to the removal of healthy ovaries, might be advised in some cases of uterine fibroids, and in uncontrollable uterine hæmorrhages, in certain malformations of the genital organs, pelvic deformities and accidental obstructions of the vagina, and in a very limited class of cases of ovarian dysmenorrhœa or neuralgia, which had resisted treatment and endangered life or reason. In nearly all cases of nervous excitement and madness he considered it inadmissible. The patient, if sane, should always be asked for her consent, the consequences of the operation being explained to her at the same time. The excision of morbid ovaries and appendages should be distinguished from oöphorectomy, and ought not to be done without due consultation, as in most other cases of abdominal section. In nymphomania and mental diseases Sir Spencer Wells considered that it was quite unjustifiable. Dr. Hegar contributed the second article in the symposium. He maintained that the removal of normal ovaries for nervous diseases was justifiable, when the operator could feel certain that the nervous symptoms were due solely, or almost solely, to disease of the sexual organs. The after-results should be watched, as the artificial menopause induced by the operation was often attended with more serious complications than those which are not rarely observed during the natural "change of life," and the operation might set up local pelvic inflammations, one of the symptoms of which complication was a periodical non-menstrual discharge of blood from the uterus. The last article in the symposium was written by Dr. Battey. He took up a different line of argument, and declared that the ovaries were themselves diseased in those cases of nervous disorders, which he classified as oöphoro-mania, oöphoro-epilepsy, and oöphoralgia. He claimed excellent results, when the operation was performed for the last two conditions, judging from cases which had been operated upon more than two years ago; but his series of those cases did not as yet exceed 36; 23 he reported "cured" and 7 "improved." It was, to a great extent, in reply to the first article in the symposium that Mr. Lawson Tait read a paper "On the General Principles involved in the Operation of Removal of the Uterine Appendages," at the Medical Society in November. He expressed great objection to some of the terms which had been applied to this operation, and agreed with the substance of Sir Spencer Wells's arguments in the symposium, although he differed in matters of detail. Above all, he declared that the presence of irreparable disease in the appendages could be diagnosed with accuracy. He had successfully diagnosed cases since 1871, and had also taught large numbers of practitioners how to make such a diagnosis. He urged that most cases of disease of that kind suitable for operation would naturally come into the hands of men who were responsible, by their position in the profession, for their proper treatment, and that would be a barrier against improper operations. In reply to the remarks of those who joined in the discussion which followed his paper, Mr. Tait observed that tentative operations, where the abdomen was opened and attempts made to unravel the ovaries and tubes by breaking down old adhesions, without amputation of the appendages, had hitherto proved unsatisfactory. The fact remained that, at the close of the year 1886, the questions, surgical and ethical, relating to removal of the appendages, remain unsettled. In connection with the same subject, the inquiry instituted this year at a Liverpool Hospital, concerning the number of operations of this class performed in its wards, and the litigation to which one case gave rise will not soon be forgotten. The pioneers of established operations all had to bear opposition and abuse. This must be remembered, and due consideration should therefore be shown to those who, without the light of the experience of others, are performing operations which are not yet established. It cannot, at least, be imputed that they hide their new ventures from publicity; on the other hand, the medical public will demand similar candour from all who follow in their footsteps.

Polymastia.—Some good monographs on supernumerary breasts and nipples, and on milk-producing tracts of integument, have appeared in the course of the year. Dr. Champneys read a paper on the latter subject before the Royal Medical and Chirurgical Society in April, in which he showed that in lying-in women the sebaceous follicles of the skin were capable of producing true mammary secretion. Dr. Neugebauer, Jun., has published a paper on a case of multiple nipples in the *Centralblatt für Gynäkologie*, and several articles on the same subject have appeared in German and Russian medical periodicals.

Foreign Gynæcological Literature.—There is no space left for a review of important contributions in foreign medical papers. Some valuable papers have appeared in the *Archiv für Gynäcologie*. The first number of a new monthly journal, the *Nouvelles Archives d'Obstétrique et de Gynécologie*, appeared in Paris last January, bearing on its title-page several well-known and honoured names. It is a journal of high merit, and its later numbers keep up the reputation of the first which was issued.

THE POOR-LAW MEDICAL SERVICE.

In the first week of the year now drawing to a close we published the decision of the Local Government Board (Ireland) on the case of Dr. Ringwood, of the Kells workhouse, who had been subjected to much persecution by a majority of his board of guardians, consequent on his reporting the unsanitary condition of the workhouse and its offices, whereby much sickness had prevailed among the inmates and officers. The subject had been referred to a committee of the board, who brought up a report denying the correctness of Dr. Ringwood's statements, and recommending that the Local Government Board should be appealed to with a view to the dismissal of that gentleman. An official inquiry was held, when it was found that Dr. Ringwood's reports were fully borne out, and the Department exonerated him from all blame, and commended him for the fearless and honest way in which he had performed his duty. The Irish Local Government Board has always manifested the desire to support its medical officers, and is therefore fearlessly appealed to whenever a medical officer feels that he has been unjustly treated by the local board. The action of Mr. Justice O'Brien at the winter assizes at Cork was also referred to at a meeting of the Poor-law Medical Officers' Association, from which it appeared that, complaint having been made by a medical witness at the insufficiency of the payment made to him, the judge not only concurred with him in such complaint, but intimated to the Crown officials that he should insist on greater liberality being exhibited towards these gentlemen, who often attended at great inconvenience and no small expense, when they gave evidence in Crown cases. He also threatened to commit such officials for contempt of court if they disregarded his injunctions. It was proposed that the judge should be thanked and the Treasury appealed to. On January 23rd we gave our decision as to the conduct of the police who were in the habit of sending for the workhouse and district medical officer to attend persons who had been picked up drunk or ill and taken to the station-house, wrongly assuming that it was part of the duty of such officer to attend such cases gratuitously; we showed that he (the medical officer) would be justified in refusing to attend, as the police had no authority to send for him, unless upon the understanding that such services were paid for. On January 30th, 1886, we again re-

ferred to the case of Mr. Stokes of the Oundle Union, who having resigned his office in consequence of the insufficiency of his remuneration, was thereupon dismissed from his appointment as public vaccinator; a non-resident gentleman was appointed in his place, though distant eight miles from the district, and that irregular—nay, illegal—appointment was confirmed by the Department on the advice of the local inspector of the district. In the JOURNAL of February 13th, page 328, we published a communication from the Oundle Board of Guardians, in which they attempted to traverse our statements, when we pointed out that our annotations were founded on reports in the local press, and that it was impossible to dispute the correctness of our observations, as they were beyond question, and, further, that they were discreditable to the administration of relief in the Oundle Union.

On page 370, February 20th, we directed attention to the action of the Royston Board of Guardians, from which it appeared that one of the guardians had given notice that he should, at the next meeting of the board, move to reduce the salaries of all the officers, when we pointed out that the officials need not be alarmed—that all attempts of such a nature would inevitably fail of effect; this turned out to be strictly correct.

On March 6th, page 469, we called attention to the decision of the Department on the interpretation to be put on the 182nd and 183rd articles of the General Orders, from whence we learn that the Department holds that a district medical officer must be in attendance at, or immediately after, a confinement, to entitle him to an extra fee for any difficulty arising out of such case; but that the guardians would be allowed to give a gratuity to any officer where exceptional circumstances arose. We understand that, although the Evesham Board of Guardians had denied that any legal claim could be maintained, yet that they ultimately awarded Mr. Haynes £1 for his extra trouble.

On March 13th, page 527, we advised a correspondent as to the fee he should charge for a consultation with a neighbouring practitioner, as to the mental condition of a non-resident lunatic pauper, when we pointed out how necessary it was that full information should be sent by the querist as to all the particulars of the case, as it was practically impossible to give a satisfactory answer when, as in the case submitted to us, such a vague statement had been forwarded.

On March 27th, page 623, we drew attention to the manner in which Mr. Bridger, a district medical officer of the Chesterton Board of Guardians, had been treated by his board. Mr. Bridger's attention had been called by some poor women to the case of an aged woman by the name of Mary Bowers, who had been found by them lying on the stone floor of her room opposite the fire-place, in which there was no fire, cold and exhausted. By great attention she was moved, put into bed, and restored. Mr. Bridger finding that she had no one to look after her, directed one of the women to see the relieving officer, tell him of her condition, and ask him either to send some person to look in upon and attend to her, or to direct her removal to the workhouse. The relieving officer having elicited from the messenger that the old woman objected to go into the workhouse, neither visited her nor sent anyone to take charge of her. Two days afterwards she was again found on the floor in front of a fireless grate, quite dead. A coroner's investigation having been held, and the relieving officer having no explanation to offer for his evident neglect, the jury censured him, the coroner remarking that, if Mr. Bridger had put his request in writing, instead of sending a verbal message, he would have had him committed for manslaughter. Subsequently this board held an inquiry of their own, at which Mr. Bridger was subjected to most disgraceful bullying. Ultimately a resolution was proposed, and unanimously adopted, exonerating the relieving officer altogether, but when a similar resolution was proposed in reference to Mr. Bridger, it was only carried by a majority of three in a board where fifteen members were present. This board has been always notorious for the high-handed and unjust way in which it has treated its medical officers. In the issue of April 3, page 665, we published the first of several annotations on the case of Mr. A. B. Simpson, senior medical officer of the Birmingham Workhouse, who had been called on by the Local Government Board to send in his resignation, consequent upon an official inquiry into his management of the establishment. Mr. A. B. Simpson has been in hot water with his board on several occasions during his tenure of office, and there has been more than one official inquiry. On a previous occasion it had been recommended to the board by the Department that Mr. Simpson should be called on to resign, but a majority of the board having pronounced in his favour, he was, though reluctantly, allowed to remain. On this particular occasion it would appear that the chairman of the Workhouse Committee had requested his attendance in certain of the sick wards, nominally with the object of investigating the condition of the drainage. At their meeting the chairman took on himself to intimate to Mr. Simpson that he had come to the conclusion that the outbreak of childbed fever which had on two or three occasions taken place was due to him, the medical officer, and that he must require him to relinquish his superintendence of such wards and turn them over to his assistant. This was done without preconcert with his colleagues; it was not put in writing, nor was the decision of the chairman communicated to the master, matron, head nurse, the clerk of the board, or to the board itself. A fresh case having subsequently occurred, a coroner's inquiry was held, when it came out that Mr. Simpson had wholly disregarded this irregular—nay, impertinent—request of the Chairman, who could have no authority for his expression of opinion, nor for his requirement. At the request of the Board, an official inquiry was held by Mr. Henley and Dr. Mouatt, who not only reported adversely to Mr. Simpson, but went the length of requiring that he should send in his resignation, not so much for previous default, but for having disobeyed the order of this chairman, calling on him to relinquish his attendance on parturient women. This comment was so utterly at variance with the generally understood principles upon which orders were given under the Poor Law—which has never recognised the right of an individual guardian to issue orders, or to exercise authority except when acting as the mouthpiece of a committee, and which requires that all such orders shall be communicated in writing to the officer and reported to the Board—and the request itself was so silly and uncalled-for, that the Poor Law Medical Officers' Association felt constrained to interfere and memorialise the Department in Mr. Simpson's favour. The only result was that, in acknowledging the letter, the Department evaded the point that had been raised, and set out in detail all the peccadilloes which Mr. Simpson had been alleged to have committed. Ultimately, Mr. Simpson, having refused to resign, was dismissed from office. In April and May nothing particular occurred, save that in the early part of the last month, Dr. Rogers, the President of the Poor Law Medical Officers' Association, became permanently disabled, owing to a severe attack of bronchitis, followed by anasarca and morbus cordis. The chest-affection had been excited by exposure to night-air, in a visit paid to the Westminster Workhouse, to see a pauper belonging to St. Saviour's Union, who, with about sixty others, had been taken in as boarders. It unfortunately happened on the night which was the very worst of last winter. The story is interesting, as it enables us to record that the board of guardians of this union expressed the warmest sympathy with Dr. Rogers, unanimously voted him a lengthened leave, and undertook to pay his deputy for him whilst he was away recruiting his health.

On page 1089 (June 5th), we reported the case of Dr. J. Hurley, of the Wincanton Union, who, on an overseer's order, had attended a case of midwifery. On sending in his claim to the board of guardians, payment was refused, on the plea that the overseer had not reported the case to them, and he was referred to their official for his fee. Dr. Hurley, having written to the Local Government Board, was shortly after informed that, if he would include this fee in his next quarter's list of extras, it should be paid. No other ending could have been expected, as it was distinctly illegal on the part of the board of guardians to refuse payment of the fee when it was first applied for. On the same page, we alluded to the rule governing the fees for performing capital operations, and what should be the course to be followed by a relieving officer when required to apply to a district or other medical gentleman in cases of pauper-lunacy.

In our issue of July 17th, page 137, will be found a report of a case which came before the guardians of the Steyning Union. It would appear that the medical officer had sent in a claim for two cases he had attended, and the clerk run his pen through the same. It would also appear that the medical officer had been called without any order to attend a poor woman in labour. But other members of the family were ill at the time and in receipt of relief. Here the guardians, after some wrangling, granted the fee. The other case was different. He had been sent for in the night, the woman having been very ill, but no order was brought. Here the Board refused to pay anything at all, whereupon Mr. Medcalf complained that it was very hard on him that he should be called out of bed and get nothing for it. We pointed out at the time how foolish it was for district medical officers to attend to cases of urgency without an order, as when the services had been rendered the majority of boards of guardians would repudiate their liability—that overseers and assistant overseers were to be found in every parish, and when an order had been obtained from one of these, the guardians could be made to pay.

On the same page, we urged upon a medical officer whose fee for certifying in cases of lunacy had been reduced by his board, to write and point out that, considering the risk which medical men are

exposed to, if with the best faith in the world they certified in cases of lunacy, it would be in the highest degree unfair to cut down the fee. We also advised that he should get his colleagues to do the same thing.

On page 387, August 21st, will be found a full report of the work of the Poor-law Medical Officers' Association, extracted from our columns for the year ending with the Annual Meeting at Brighton. That meeting of the Poor-law Officers' Association was very well attended, and was rendered interesting by the very great sympathy expressed with Dr. Rogers in the serious illness which had overtaken him, and which had compelled him to resign his poor-law appointments, and his practice generally, of which more hereafter.

In the same issue will be found a reply to a question, submitted to us by a Scotch parochial medical officer, as to his dismissal from his appointment, and inquiring whether he would be entitled to compensation, and to whom he should apply. On page 398 will be found both question and answer, as well as the reply to the question of leave of absence, etc., and the fee for the examination of a lunatic.

On page 608, September 25th, will be found an annotation on the success which attended the spirited effort made by Dr. J. B. Cane, Dispensary Medical Officer of the Waterford Union, to get an increase of the amount of fee for visiting and reporting on the condition of labourers' cottages from 5s. to 10s. 6d.

On page 657, October 2nd, we published the resolution adopted unanimously by the Westminster Board of Guardians, at the meeting of that Board on September 27th, when Dr. Rogers's letter, announcing that, owing to continued ill-health, he was compelled to resign his appointments, was read.

On page 795, October 23rd, will be found another illustration of the readiness with which Poor-law medical officers will visit paupers, in cases of urgency, without any order, expecting that their boards will pay them the customary fee. We have so frequently advised them as to the course they should follow, that we much fear that many of them could not have read what we have written for their guidance.

On page 955, November 13th, will be found a report of the proceedings of the Westminster Board of Guardians, at their meeting on Nov. 5th, when the question of the superannuation of Dr. Joseph Rogers—notice for which had been given by Mr. Samuel Bonsor—who, for nearly sixty years, had represented the parish of St. Anne's, Soho, first on the Strand, and for the last eighteen years on the Westminster Union, came on for discussion. The Board was unanimous that superannuation allowance should be granted for the fourteen years he had been medical officer of the Westminster Workhouse, but a minority held that it should not be given for the twelve years he had held a similar position at the Strand. The majority took a contrary view, and it was based on these grounds—that St. Anne's, Soho, formed part of the old Strand Union, up to the time that the union was broken up in 1868, and that it was during the preceding twelve years, that Dr. Rogers had attended the sick-poor of this parish, which was the largest and most populous parish in that Union; that on the resignation of Mr. French, the fund, from which that gentleman was paid his superannuation allowance, was derived from St. Anne's and St. James's conjointly, seeing that that parish was, in 1868, joined on to St. James's to constitute the Westminster Union, and seeing also that Mr. French had never attended the in-door sick of St. Anne's at all. The Board was desirous of granting to Dr. Rogers the largest superannuation allowance in their power, and if the amount had been determined on the services rendered to the Westminster Union only, the grant would have been very small.

By the sanction of the Local Government Board to the grant being made for the services rendered to both parishes, an important precedent has been established, which it would be well for Poor-law medical officers to bear in mind.

In our issue of December 4th, page 1128, in answer to a correspondent who had written for our advice, we pointed out what was his duty in reference to weak-minded and imbecile persons so frequently to be found in workhouses, namely, that their names should be entered in a book specially provided for the purpose; that the fact of such entry should be brought to the knowledge of the master and and matron, who should have charge of such book; and that the entry in question should be understood by these officials to imply that the imbecile, or weak-minded person, could not be allowed to leave the workhouse; and that the book should be laid on the board-room table at each meeting of the board, and be open to any poor-law inspector or commissioner in lunacy who may visit the workhouse officially.

PUBLIC MEDICINE.

A Barren Session.—Work of Parliamentary Bills Committee.—Lunacy Acts Amendment Bill.—Burgh Police and Health (Scotland) Bill.—Regulation of Dairies.—"Milk Scarlatina." Sanitary Survey.—Unhealthy Health-Resorts.—Typhus Fever.—The Plumbers' Company.—The Metropolitan Asylum Board.—Metropolitan Water-Supply.—Small-pox in Montreal and Jamaica.

A Barren Session.—The ordinary current of public affairs has been so seriously deranged by the continuous discussion of Irish grievances and by the changes of Ministry, that the year has been almost barren of useful domestic and sanitary legislation. The reform of local government has made no visible progress, though a comprehensive measure would appear at last to be in preparation by the Government under the guidance of Mr. Ritchie, the President of the Local Government Board. Its introduction to Parliament, at the earliest possible moment, has been promised, but its active prosecution must depend upon the time occupied, when Parliament meets, in reforming the procedure of the House of Commons, and in effectually stemming the tide of obstruction.

The Parliamentary Bills Committee.—The political interests of the medical profession have, as hitherto, been carefully looked after by our Parliamentary Bills Committee; but, for the reasons already indicated, there was comparatively little opportunity for effective action by the Committee. A full report of the Committee's proceedings will be found at page 275 of the JOURNAL for August 7th.

The Lunacy Acts Amendment Bill of 1885 was reintroduced last session by Lord Chancellor Herschell, with large modifications; but, owing to the defeat of the Government, the Bill was withdrawn. The Subcommittee of the Parliamentary Bills Committee, that had been appointed specially to consider the subject, had, however, secured the incorporation in the measure of a number of important recommendations. If the amended Bill be again introduced, and be passed with some comparatively slight alterations, it will be a great boon to the insane, and to those who have to assume responsibility with regard to them.

Burgh Police and Health (Scotland) Bill.—This bulky Bill has been introduced in four successive sessions of Parliament, and during the past session it made practically no progress. Before such a measure becomes law, a careful inquiry is needed into the whole question of the relations of private medical men with local sanitary authorities as regards cases of infectious disease occurring in their practice.

Regulation of Dairies.—The only piece of general sanitary legislation of the year consists of a single clause, which, owing in great measure to the persistent representations of the Parliamentary Bills Committee in past years, was incorporated in the Government measure amending the Contagious Diseases (Animals) Act of 1878. By this clause (No. 9) the duty of regulating the sanitary arrangements of dairies, cowsheds, and milkshops is transferred from the Privy Council and the Courts of Quarter Sessions to the Local Government Board and the local sanitary authorities throughout the kingdom. We recently took occasion (in the JOURNAL of December 4th, page 1127) to comment on this involved and somewhat clumsy clause, and we pointed out that, although the object which it aimed at is one of paramount importance to the public health, and one which should have been secured many years ago, yet the amendment of the law is by no means as complete and satisfactory as it might have been. No doubt the haste with which the Bill had to be passed through its various stages prevented the details of the scheme from receiving their due share of attention. The chief defect of the measure consists in the fact that sanitary authorities and their officers have no recognised right given them to make observation of diseases in the cows themselves in cases where the purity of the milk is in question. Even the veterinary authorities, in dealing with "diseases" as defined by the Act of 1878, are restricted to cattle-plague, pleuro-pneumonia of cattle, and foot-and-mouth disease. Neither tubercle, anthrax, nor scarlatina in the cow is under regulation or observation.

"*Milk Scarlatina.*"—This last consideration is of especial importance, in view of the researches which have been undertaken, and are still being pursued by Mr. W. H. Power and Dr. E. Klein, F.R.S., under the direction of the Local Government Board, as to the possible relation of scarlatina in the human subject to a disorder having similar characters in the cow. These researches were first undertaken in consequence of the observations which Mr. Power made, in the early part of the present year, when investigating a severe and curious outbreak of scarlatina in some London districts that had derived their milk supply from a farm at Hendon; and in a very interesting and important report on the subject, issued some months ago by the depart-

ment, it was demonstrated beyond reasonable doubt that the outbreak of scarlatina in question was dependent upon a diseased condition of the milch cows at the farm—a condition which was first introduced by some recently-arrived animals, and which subsequently spread among the animals after the fashion of an infection. Dr. Klein's scientific investigations on this subject are still being carried on, and we have reason to believe that the report of them, which is promised to be given in the forthcoming report of the medical officer of the Board, will be found strongly to confirm previous observations as to the relation of disease in the cow to the infective property which may be found in the milk of that cow.

The Sanitary Survey.—The continued presence of cholera in southern Europe, with which we have dealt in a separate article, has tended to keep alive in a special manner the public interest in promoting good sanitary conditions throughout the country. It is satisfactory to find that the Local Government Board has not failed to make use of the possible appearance of cholera to induce negligent authorities to undertake sanitary improvements which, apart from cholera, are needed to resist typhoid and filth-diseases generally. With this object, the Board's medical staff have continued during the past year the sanitary survey of the country which they began in 1884. The survey of the port and riparian districts was under the more immediate supervision of Dr. Blaxall. That of inland districts was guided by Dr. E. Ballard, and included investigation of the cleanliness, sewerage, and drainage, the methods of excrement and refuse removal, water-supply, the condition of dwellings, the means for isolation of infectious disease and for disinfection, and the general sanitary administration, of the districts visited. The blue-book on Cholera recently issued by the Department gives a full account of the survey work up to March last, and from it we gather that, on the whole, we are now immeasurably better prepared to resist cholera than we were twenty, or even ten, years ago. The sanitary arrangements of port and riparian districts, upon which our security against the spread of cholera must very greatly depend, have been found excellent in some places—such as London, Tyne Ports, Liverpool, Swansea, Cardiff, Newport and Bristol—but in others seriously defective—such as Plymouth, Cowes, Hartlepool, Dartmouth, Exeter and Grimsby. The whole of the inspectors' reports, which are analysed at some length in the Blue-book already mentioned, show that the duty of caring for the public health is becoming increasingly appreciated by English communities, and that the recent survey (which we are sorry to understand was discontinued at the end of November) will have conduced to a more general fulfilment of sanitary duty by the representatives of those communities.

Unhealthy Health resorts.—During the year we have on several occasions found it necessary to call attention to the defective sanitary arrangements of several of our so-called health-resorts. Newquay, Cowes, Shoreham, Swanage, and others, have all called forth adverse criticism. It is to be hoped, in the interest of the prosperity of those places, as well as of persons who resort to them in search of health, the local authorities will no longer delay to remedy the unwholesome conditions that have been revealed.

Typhus Fever.—With the advent of winter, and the season of distress, we hear of the presence of typhus in some of our large towns. Cases have been recently reported in Liverpool, Leeds, and Middlesbrough.

The Plumbers' Company.—During the year this ancient City guild has entered on a new sphere of usefulness. Since sanitation first became a recognised science it has been a matter of very general complaint that much of the work done by so-called plumbers has been "scamped," and that as a consequence the health of individuals and of communities has frequently been endangered. With a view to meet this well-founded complaint, the Plumbers' Company has organised a system of registration of properly qualified plumbers, which has already received the recognition of the President of the Local Government Board, and of the leaders of sanitary science, and which deserves the support of sanitary authorities and sanitary officials generally.

The Metropolitan Asylums Board.—The difficulties which have of late years waited upon this board in their endeavours to provide adequate hospital accommodation for metropolitan small-pox cases are too notorious to need any detailed reference here. Suffice it to note that the results of Mr. Power's investigation, referred to in our last Retrospect, of the influence of the Fulham Hospital on the prevalence of small-pox in the immediate neighbourhood, and the evidence which the Local Government Board have acquired in support of those results, have greatly influenced the board in their dealings with this question. They have consequently shown considerable hesitation to take the responsibility of approving any scheme which would entail the aggregation of numerous cases of small-pox in one locality.

Metropolitan Water-Supply.—In connection with the further powers which the East London, Lambeth, and Southwark and Vauxhall Water Companies obtained from Parliament during the past year, it is of interest to note that the new powers of raising additional capital were given on such conditions as will ensure to the ratepayers and water-consumers a share of the profits that will be earned by such new capital; and the formation of a fund towards purchasing the undertakings in the public interest has also been provided for. During the autumn, serious complaints were made respecting the presence of eels in the mains of the East London Water Company. These creatures gained admission to the mains some years ago, through an accident to the filter-beds; and according to the evidence of the health-officers of West Ham, serious illness has, in several cases, been caused through the use of water from a service-pipe in which an eel had become entangled, and had decomposed. The company are prosecuting their difficult, but absolutely essential, duty of ridding their mains of eels and fish. Another source of danger to the consumers of the water supplied by those companies that draw from the Thames, is the discharge into the river, a few miles above the intake of the water-companies, of the crude sewage of Staines. This subject has for several years been under consideration by the Staines sanitary authority, and is one which needs to be immediately dealt with.

Small-pox in Montreal and Jamaica.—Apprehension has existed at some of our western ports lest small-pox should be introduced from Montreal or Jamaica, where the disease has been prevalent. A case actually did occur on board a vessel which arrived at Bristol from the former place, but proper precautions prevented any mischief resulting. In Montreal, small-pox was severely epidemic in the later months of 1885, and extended into the early months of the present year. Before it died out it had taught an instructive lesson as to the efficacy of vaccination as a prophylactic of small-pox, inasmuch as the disease was confined almost exclusively to the unvaccinated, whose ranks, especially amongst the French portion of the community, have unfortunately been greatly swelled of late through the assiduity of some anti-vaccination agitators. In Jamaica, small-pox broke out on March 12th last, and has since prevailed persistently in the island. Up to November 3rd, there had been about 1,800 cases and 256 deaths since the outbreak, and, of these, 1,090 cases and 190 deaths occurred in the town of Kingston. There is thus a curious, but at present unexplained, higher proportion of deaths to cases in Kingston than in the remainder of the island. Stringent measures have lately been adopted by the Colonial Government with the view of stamping out the epidemic.

PARLIAMENTARY BILLS COMMITTEE.

Lunacy Acts Amendment Bill, 1886.—Early in the year (see BRITISH MEDICAL JOURNAL, February 27th, 1886, pp. 415-6) the Parliamentary Bills Committee appointed a Subcommittee to consider the provisions of the Lunacy Acts Amendment Bill, 1886, introduced by the Lord Chancellor in the House of Lords. The Subcommittee adopted a series of suggestions, embodied in a memorandum, which, together with an introductory letter, was transmitted to the Lord Chancellor. Of these suggestions, the most important were:

(1) That the same degree of protection as was afforded by the Bill to those who sign certificates of insanity should be extended to those who have the care of the same patients subsequently.

(2) That the Bill should be amended by omitting the prohibition contained in it of the reception of a lunatic (other than one of those so found by inquisition) as a "single" patient; that is to say, in a house unlicensed for the reception of lunatics.

(3) That the clauses confiscatory of the property of private asylum proprietors should be omitted or modified, or the question of compensation entertained.

(4) That the provision should be modified by which any lunatic might be examined at the request of anyone, and discharged, if certain certificates could be obtained.

(5) That the provisions relating to workhouse medical officers should be modified; as also those relating to periodical reports and certificates from asylum medical officers.

A courteous reply was received from the Lord Chancellor, and, after consideration, several of the suggestions of the Committee were practically adopted by the Lord Chancellor, who introduced amendments of the Bill, in committee or recommitment in the House of Lords, making material, and, in some cases, fundamental changes in the operation of the Bill. Particularly was this the case with respect to the suggestion as regards "single" patients, and that concerning the clauses of the original Bill having confiscatory effects on private asylums. Other less important suggestions were also adopted. Yet the amendments of the Lord Chancellor with regard

to single patients introduced a departure from the general method of the Bill, both as regards the requirement of an order of the "Judge in Lunacy," and as regards the arrangements (liable to abuse) with respect to cases certified to be suffering from temporary unsoundness of mind, or senile mental decay, or to be desirous of voluntarily submitting to treatment. Another departure, of inexpedient nature, was the omission of the existing magisterial examination in pauper cases.

In a second memorandum, suggestions were forwarded to the Lord Chancellor (1) with respect to the extension to all medical men concerned in lunacy cases of the provisions of the Bill protective of the signers of certificates; (2) with respect to the release of lunatics under the method provided in the Bill, as already referred to; (3) with respect to the complex and detailed reports and certificates required from asylum medical officers in the Bill; and (4) with respect to the punitive clauses of the Bill bearing on workhouse medical officers, and that bearing on their non-remuneration. Shortly after this, the political crisis led to the withdrawal of the Bill; and the whole subject stands over till the next session of Parliament.

THE CHOLERA.

Cholera in Italy, Austria-Hungary, Spain, France, Japan and the Corea, and India. — Precautions taken in England. — Cholera on board a Troopship. — Dysentery at Riga.

EVER since cholera first made its appearance at Toulon in June, 1884, it has, like a spectre, been hovering over Southern Europe. Fortunately, but for no well-defined reason, it has not extended to Northern Europe, although for three seasons it has been threatening to do so. In a recent number of the JOURNAL (October 23rd, page 772), we gave a summary of the havoc which cholera wrought in 1884 and 1885; and from that summary it may have been observed that the disease, once started at Toulon and Marseilles, seemed to radiate northwards to Paris, and eastwards throughout the Italian Peninsula; whilst Spain, to the south-west, was soon afterwards invaded and terribly scourged. During the year just ended, however, the disease seems to have somewhat changed its points of attack, and has centred more particularly in the western and northern shores of the Adriatic, whence it spread north-eastwards through Carniola and Croatia, to Agram, Raab, Pesth, and Szegedin; and south-eastwards to Priedor and Novi in Bosnia, Belgrade in Servia, and even Tirnova in Bulgaria.

Cholera in Italy.—During December, 1885, sporadic cases were reported from Venice. This prevalence continued until the end of April last, by which time 116 cases and 80 deaths had occurred in the city since the beginning of the year. Early in May a sudden and rapid increase took place in the number of cases, and in the first week of June as many as 218 cases and 132 deaths were reported. The disease continued in Venice, with decreasing severity, until October, when the city was declared to be practically free from it. Altogether, not less than 1,000 cases, with about 620 deaths, have occurred in the city during the past year. It may here be noted that in some quarters it was asserted that the Venetian disease was not true Asiatic cholera, whilst others described it as "choleraic typhus." Meanwhile, however, an epidemic of undoubted Asiatic cholera was rapidly spreading in the south-eastern provinces of Italy. The disease broke out early in April at Brindisi, which is situated in a flat unhealthy locality, and by the 15th of that month 72 cases, of which 15 were fatal, had occurred in the town. From Brindisi it spread rapidly to the adjoining towns of Latiano, Francavilla, Fontana, Lecce, Bari, Barletta, etc., creating panic in the neighbourhood, and anxiety in the whole country. The sanitary arrangements of these places seem to be bad in the extreme, and, at Latiano especially, the polluted wells are charged with having been mainly instrumental in spreading the disease. During the summer, the towns of Chioggio, Treviso, Padua, Ferrara, Ravenna, and others in the valley of the Po, and in the neighbourhood of Venice, suffered somewhat severely from choleraic sickness. A few cases occurred at Torre Annunziata, near Naples, early in September, and at Rome in October. In September, Sardinia was invaded; but, although the disease was virulent in character, it does not seem to have diffused itself widely in the island. In the middle of October, cases were reported from Genoa, and further cases followed during November; but no cases appear to have occurred in the town, or, indeed, in the whole peninsula, since the 27th of the last mentioned month. It is estimated that up to the middle of October, when cholera as an epidemic may be said to have come to an end in Italy, 21,000 cases and 8,650 deaths had occurred throughout the peninsula. Some towns of Italy seem to have profited by their past experiences of cholera, and by the teachings of the Roman Sanitary Conference of last year. In Rome itself nearly all the wells have been filled up, and a wholesome supply of water provided, much to the benefit of the public health. Naples also seems to be improving its hygienic conditions. But at Florence, where it is asserted that the well-waters are very generally grossly polluted, and that cesspools of the worst sort prevail, there seems still to be great reluctance to effect the needed sanitary improvements.

Cholera in Austria-Hungary.—In December, 1885, occasional cases of cholera were occurring in Trieste, a town of about 135,000 inhabitants, situated at the extreme north of the Adriatic Sea, and of special importance as constituting the centre of Austrian foreign commerce. The disease died out in this town about Christmas, 1885, but broke out again on June 7th last, and from this centre rapidly spread through Fiume, Istria, Carniola, Gorizia-Gradisca, Croatia and Dalmatia, and into Bosnia and Servia. It is officially reported that, up to the middle of November, when the virulence of the epidemic may be said to have passed, about 900 cases, and 550 deaths, occurred in Trieste alone, and that in the province of Istria 672 cases, and 374 deaths, had occurred. Bad hygienic conditions prevail in all these districts. In some places the populace are reported to have been guilty of acts of barbarism, such as was common last year in Spain. They accused the local doctors of poisoning them, and in some cases actually resorted to violence. On September 12th cholera broke out in Pesth, where its advent had for some time been dreaded. It rapidly spread, owing to the execrable sanitary arrangements of the town, and before it died out, about November 20th, more than 1,200 cases, and 500 deaths, had occurred. Very severe censures were passed on the unpreparedness of the town to resist the cholera. The water-supply was described as being at all times indifferent in quality and inadequate in quantity, and it was said that over 30,000 of the inhabitants—a tenth of the total population—lived in damp underground rooms, where ventilation, a proper supply of water, and cleanliness were impossible. The town of Raab, which is situated on a tributary of the Danube, about half-way between Pesth and Vienna, and Szegedin, which is about 100 miles to the south-east of Pesth, suffered to some extent at the same time as the Hungarian capital. As in the case of Venice, some doubts have been expressed as to whether all the cases at Trieste returned as "cholera" were cases of the true Asiatic disease, and it has been noticed as a significant fact that during the summer no cases of diarrhœa or dysentery were recorded in Trieste, although those diseases are usually common there.

Cholera in Spain.—Spain has suffered comparatively little this year from cholera. In January the disease was still lingering in Malaga and Algeciras, where it had caused such great mortality during the previous summer; and during the first three months of the year a considerable number of cases occurred at Tarifa, not far from Gibraltar. But the disease seems then to have disappeared from Spain until October, when a fresh crop of doubtful cases was reported from Malaga.

Cholera in France.—France also has had but little cholera this year, but the little that it has had, occurring as it did in the Department of Finistère, close to our own shores, has had especial interest for England. No cases, so far as is known, have occurred in Finistère since May last; but during the first four months of the year the disease undoubtedly prevailed to an appreciable extent at Brest, Concarneau, Douarnenez, Audierne, and other places in that locality.

Cholera in Japan and the Corea.—Whilst we have been watching the progress of cholera nearer home, the disease seems to have been ravaging the greater part of the Corea, and to have caused great mortality in Japan. Exact statistics are not yet obtainable, but it is reported that in Japan not less than 50,000 persons have been attacked, and 35,000 have died; whilst in the Corea the population has been decimated.

Cholera in India.—India, the home of cholera, is never free from the disease; but during the past year there does not seem to have been any exceptional prevalence—at least in the three principal towns. As regards Calcutta, the fortnightly official returns during the first ten months of the year showed, as a rule, a mortality under the average of the previous five years; but since October 25th there has been a rapid and considerable increase in the cholera mortality in that city. From January 1st to December 8th, altogether 1,553 deaths from cholera had occurred in Calcutta, as compared with 1,836, the mean for the same period of the preceding quinquennium. In Bombay, during the same period, only 15 deaths occurred, as compared with 510, the mean of the same period of the previous five years. No deaths seem to have been recorded in Bombay during the months of July and August, and none since September 29th. In Madras, no death had been recorded since February 13th last.

Precautions taken in England.—We have shown, in a separate section devoted to "Public Medicine," that England is not unprepared

to resist the introduction of cholera. By way of special precaution, our Government has during the year prohibited, from time to time, as it has done on former occasions, the importation of rags from certain infected countries, and it has also made strenuous efforts to promote good sanitary conditions at our ports and throughout the country generally. In view of the somewhat special circumstances of the sea-approaches of Cardiff, the Government found it necessary to provide temporarily a steam tug to enable the Customs authorities, in carrying out the Cholera Order of the Local Government Board, to examine vessels from abroad before they entered the harbour.

Cholera on Board a Troop-Ship.—No case of cholera has actually reached our shores during the year; but, on October 24th, it was reported that four deaths from that disease had occurred on board Her Majesty's troop-ship *Euphrates*, then homeward bound from India. When the vessel reached Suez, the Egyptian authorities proposed to impose the stereotyped "quarantine at El Tor;" but, on the English Government threatening to send the vessel home by way of the Cape rather than submit to such an unnecessary, if not indeed perilous, proceeding, the vessel was allowed to pass through the Suez Canal "in quarantine." It should be noted that, by the time the vessel had arrived in the Red Sea, there was no choleraic sickness on board. The vessel arrived in the Solent on November 16th, and as medical examination revealed no sickness among the troops on board, they were landed, with all due precautions, and proceeded to their homes, without any evil results to the public health. The vessel was thoroughly cleansed and disinfected, and has since returned to India. Had any choleraic sickness or source of infection been found on board, the patient would have been isolated in the Government hulks at the Motherbank, which are always in readiness for such an emergency.

Dysentery at Riga.—It may be interesting here to note that, early in September, a severe outbreak of dysentery occurred at Riga, on the Baltic.

THE NAVY MEDICAL SERVICE.

THE Royal Navy has happily surmounted all difficulties in getting candidates, who increase in numbers at the six-monthly examinations; and it is now rarely that the name of a young surgeon is seen amongst those of officers "resigned." These are sound indications of prosperity, which, it may be hoped, will long endure. Promotion in the higher ranks has been unusually rapid, owing to early retirements, which is the greatest inducement to keep on active service. In the year there have been two deaths of retired Inspectors-General—Sir James Salmon, M.D., and Dr. J. Urquhart Bremner—both of whom had good war records. By the death of the former, a good-service pension of £100 a year falls to the patronage of the Admiralty. There is already some curiosity to see an early announcement of the name of the officer to whom this will be given, and the general opinion is that it will be on a senior officer who has received the very highest honours and decorations attainable for conspicuous meritorious services at seats of war, as well as in the chief naval hospitals. It may be asserted that a strong presentiment is entertained that the coming year of jubilee will not be allowed to pass without recognition by the granting of fresh honours. Both of the Royal services remember that the lists of medical officers once contained names with the rank of baronet accorded for services in war. It is now hoped that on so glorious an occasion, in which the heart of a whole nation will rejoice, the gracious hand that laid open to her medical officers the decorations of the Order of the Bath will be pleased to restore to their calling, and to place within their reach, the more enduring recognition of skilful medical services rendered to the Crown, for which precedents exist.

THE ARMY AND INDIAN MEDICAL SERVICES.

Army Medical Service.—Brigade-Surgeons in India.—The Volunteer Medical Staff Corps.—Personal Events and Changes in the Army Medical Service.—Indian Medical Service.

Army Medical Service.—The year which is just approaching its close has not been marked by any stirring events in the medical department of the army. The active operations in Egypt, which had led to large demands on the resources of the medical department, in order to provide for the hospital needs of the Nile expedition, and of the expeditionary forces in the Eastern Soudan, had ceased before the year commenced; and since the conclusion of those operations no fresh demands have been made on the department in England to arrange for war service. A large number of medical officers of the British army are on active service in Burmah with the various regiments and corps engaged in that country, and in the general and field hospitals established for the sick and wounded of the British troops; but, as the Burmah expedition is controlled and directed by the Indian Government, the medical arrangements for the whole of the forces engaged in it have been made in India.

Several interesting reports of the medical and surgical transactions connected with the military operations in Egypt in 1885 have appeared during the present year. They have been published in the form of a series of appendices to the Army Medical Department volume of statistics which was issued in July last, and it is a matter of regret that they have not been issued in some more widely-known and more accessible shape. Surgeon-Major G. B. Mouat, M.D., has written the medical history of the Nile expeditionary force from the 18th of March, 1884, to the 31st of July, 1885. His report embraces an account of the wounds and injuries received in the several actions during the advance on Khartoum, and in the subsequent engagements with the enemy, as well as of the diseases which were prevalent among the troops in the expedition. Several reports on the medical and surgical transactions of the Suakim expeditionary force in the Eastern Soudan have also appeared, the principal one having been furnished by the late Surgeon-General Barnett, who was chief of the medical staff with the expedition. A copious and interesting medical history of the followers—native, Arab, and European—who were attached to the British forces in the same expedition, has been written by Surgeon Hendley, of the Indian Medical Service; while other papers of value bearing on the medical history of the campaign have appeared—namely, a report on the work done on the Hospital Ship "Ganges" attached to the expedition, with observations on hospital ships in general, by Brigade-Surgeon Gribbon, M.S., and a paper of notes on the hospital equipment used during the military operations in the neighbourhood of Suakim, by Surgeon-Major J. Fleming, M.D., M.S. A considerable amount of medical and surgical experience gained during the two military expeditions in Egypt has thus been placed on record, and will remain available for future reference.

Brigade-Surgeons in India.—The medical officers of the British Medical Service holding the rank of brigade-surgeon, who are serving in India, still labour under the disadvantage of their grade not being recognised by the Indian Goverment so far as pay and allowances are concerned. We have received many communications on this subject in the course of the year, and have more than once expressed our opinion on the justice of the claims put forward by these officers. When due regard is given to the higher qualifications which the brigade-surgeons must be proved to possess before they can attain the grade, and when the advantages to the Indian Government are remembered which must result from this professional superiority in the posts of responsibility and importance in which the brigade-surgeons are usually employed, there can be little difference of opinion that it would be only wise and just for the Indian Government to recognise the title of the brigade-surgeons to a higher scale of pay and emoluments, on a basis corresponding with that on which the rank and pay of the same officers are dealt with by warrant when they are serving on the home establishment. We trust that, long before a retrospect of another year is required, the policy of conceding the just claims of the brigade-surgeons in India will be acknowledged by the Indian Government, and that the grant of a suitable staff-allowance to them will have been ordered. A movement has lately been set on foot to bring the matter to the notice of the Secretary of State for India, and the remarks referring to the subject that have appeared in our columns sufficiently indicate the desirability of a speedy settlement of the point at issue.

The Volunteer Medical Staff Corps.—The medical department of the Volunteer forces of this country has acquired a very considerable development during the past year. Like the artillery and engineer volunteers, and the various volunteer rifle corps, the Volunteer Medical Staff Corps now occupies a regular and distinct place in the official Army List. The names of the medical officers of the volunteer battalions still appear with their respective corps, while those of the Volunteer Medical Staff are separately shown in connection with the lists of officers of the Medical Staffs of the army and militia. This expansion of the Volunteer Medical Service is an important advance in its organisation, for it is evident that the more closely the Volunteer Medical Department is assimilated in its constitution to that of the Medical Department of the regular army, not only will its efficient working be more to be depended upon on occasions when the volunteer forces are brought together in large numbers, but the more useful will the Department become as an adjunct to the regular army medical service. The interest in military medical arrangements has become so much more widely diffused, and the subject has acquired such popularity throughout the country—partly owing to the full reports published in the journals of the day of field-hospital matters during recent campaigns, partly owing to the training of a considerable number of volunteers in stretcher drill, in the duties of bearer com-

panies, and other such exercises connected with service in the field; and in a certain degree also, perhaps, to the instruction given in all parts of the country in the classes of the St. John Ambulance Association—that it is easy to foresee that the movement which has advanced so far during the past year is destined to make still further strides in the future. There seems to be good reason for anticipating that the Volunteer Medical Staff Corps will shortly form a valuable reserve for the Army Medical Department. In case of an European war on a large scale, or in a war of extended duration, instead of the untrained civil practitioners who have been engaged in some former wars by the Government to fill up the gaps in the ranks of the regular service, the Volunteer Medical Establishment will constitute a body to which the Minister for War may resort with confidence for a supplementary supply of medical officers, stretcher-bearers, and hospital assistants, already disciplined and in a great measure familiar with the regulations and ways of military service. The position which is now given to the Volunteer Medical Staff Corps in the War Office Army List plainly indicates that some arrangement of the kind mentioned is looked forward to by the military authorities who have the direction of such matters.

Personal Events and Changes in the Army Medical Service.—The changes in the department include the retirement from the active list of two of the senior Surgeons-General—Dr. G. Auchinleck and Sir A. D. Home, V.C., K.C.B., both of whom attained the regulation limit of age for the grade during the present year. Sir A. Home had long been one of the most distinguished members of the medical staff. He gained the Victoria Cross for his gallant and courageous defence of a convoy of wounded under his medical charge in the advance on Lucknow at the time of the Indian Mutiny, and was made a Knight Commander of the Bath for his services in preparing and directing the medical arrangements of the Ashanti War of 1873-74 under the command of Lord, then Sir Garnet, Wolseley. He has been succeeded in the post of principal medical officer of the southern district, which he was holding at the date of his retirement, by another medical officer decorated with the Victoria Cross, Surgeon-General H. T. Reade, who also obtained the distinction for conspicuous bravery during the Indian Mutiny campaign, at the siege and assault of Delhi. The losses from death during the year have been numerous, both in the active and retired lists of the department. Among the officers in active employment, there have died Deputy Surgeons-General Wm. Skeen, M.D., A. Guthrie, and W. H. Corbett, M.D.; Brigade-Surgeon T. Oughton; Surgeons-Major A. Thomson, M.D., T. W. Orwin, T. R. Lewis, M.B., T. M. Kirkwood, F. Falwasser, R. B. Smyth; and Surgeons J. F. McCraith, H. S. Parker, F.R.C.S., G. S. O'Grady, J. Heath, M.B. (killed in action in Burmah), and T. Pedlow, M.D. The deaths among the medical officers on the half-pay and retired lists have included those of Surgeons-General H. L. Cowen and E. Gilborne; Inspectors-General Dr. A. Gordon, C.B., and T. R. Jameson, M.D.; Deputy Surgeons-General R. W. Read, C. G. Logie, M.D., J. Madden, W. G. Trousdell, M.D., W. L. Farmer, and J. McNab, M.D.; Brigade-Surgeons W. H. Pickford and T. Ramsay; and Surgeon P. Nicholson, M.D. Surgeon-Major T. R. Lewis, who died at the comparatively age of 44 years, had already acquired a European reputation, from his discovery of the *filaria sanguinis hominis*, and from his numerous investigations in the field of pathology. At the time of his death he was holding the position of Assistant Professor of Pathology in the Army Medical School at Netley. A notice of the career and scientific works of this distinguished army medical officer has been given in the JOURNAL of June 26th. It has been announced that his scattered writings and reports are being collected, and that they will shortly be published in a separate volume. Among the interesting events of the year may be mentioned the reception, on November 22nd, by the Army Medical Department mess at Netley of the portrait of Surgeon-General Maclean, C.B., who had held the professorship of tropical medicine in the Army Medical School for a period of nearly twenty-five years, and had retired from the position in the early part of last year; together with the presentation, about the same time, of a replica of the picture to Mrs. Maclean at the residence of Professor Maclean in Southampton, by a deputation of the subscribers to the testimonial fund from which the portraits had emanated. A report of the proceedings on these two occasions has recently appeared in our columns.

Indian Medical Service.—The military operations in Burmah have led to the necessity of medical assistance being provided on a large scale for the expeditionary forces, and the arrangements for the field hospital establishments and ambulance transport have been made in India on what appears to be a sufficiently liberal basis. Between the general hospitals at the base of the military operations and the advanced forces, a series of floating and travelling hospitals and flats have been formed, the flotilla not only being provided with the necessary fittings for hospital accommodation, and the means and appliances for the treatment of the sick and wounded of the European and native troops, but also carrying extra field-hospitals complete, with camp equipage and transport, ready to be sent forward, at any moment in case of need, with bodies of troops that may have to operate at a distance from the river. A great strain has been thrown upon the Indian medical establishment as regards the supply of medical officers, including those of the British medical service doing duty in India, as well as those of the Indian department, in order to meet the wants of the hospital establishments with the army, and the needs of the numerous detachments of troops which have been posted at various points over the theatre of conflict. The chief hospital ship, the *Rangoon*, is described as a spacious and well-fitted passenger steamer, admirably provided in every respect for the purposes to which it is temporarily devoted. Deputy Surgeon-General Donnelly, of the Indian Medical Service, has acted as principal medical officer of the expeditionary army. A new organisation of the administrative staff of the Indian Medical Service came into force in the spring of the year. Up to March 19 last the sanitary commissioners of the various provinces were entitled to the rank and privileges of deputy surgeons-general of the military service, in virtue of their holding the positions of sanitary commissioners. This rule ceased at the date mentioned, but it was still ordered that all Indian medical officers in civil employment would remain liable to be called on for military duty in the event of their services in a military capacity being required, and that when not wanted for military service they should be regarded as temporarily lent to the civil departments. At the same time, the duties of the sanitary commissioners with the Government of India, and with the governments of Madras and Bombay, and their relations to the sanitary commissioners attached to local governments and administrations, were more plainly defined than they had been in previous orders. The sanitary commissioners were constituted the heads of the Indian medical departments in their respective Presidencies, and were made responsible for the discharge of all the civil administrative duties in their respective provinces. New scales of pay were ordered for the various administrative appointments, and we are led to believe that, with a few exceptions, the new organisation has given general satisfaction to the Indian medical service.

The death of Dr. Norman Chevers, C.I.E., who retired a few years ago from the active list of officers of the Indian Medical Service, has been recently announced. The services of this very distinguished public servant were of many years' duration, and his professional relations with the Government of India, together with his work as a teacher in the Medical College of Calcutta, and as an author of numerous valuable publications, exerted an important influence on medical and sanitary progress in India. A sketch of the career of Dr. Chevers, together with a list of his writings, appeared in last week's JOURNAL, and it is only necessary, therefore, to revert to the fact of his decease in this retrospect, and of the great loss which the Indian Medical Service and the medical profession have sustained in this event.

MEDICAL EVENTS OF THE YEAR IN SCOTLAND.

EDINBURGH.

The Edinburgh School of Medicine and Female Students.—Dr. Gunning's Donation.—The Royal College of Physicians.—Post-Graduate Course.—Fever Hospital and Clinical Instruction.—The University.—Direct Representation on the Medical Council.—Medico-Chirurgical Society.—Medical Staff Corps.—Royal Infirmary.—Abuse of Medical Charities.—Small-Pox.—Rabies.—Ambulance Movement.—Small Hospitals and Convalescent Homes.—Obituary.

The Edinburgh School of Medicine and Female Students.—The year about to close has been marked by some noteworthy events. Through the indefatigable efforts of Miss Jex-Blake, the Edinburgh School of Medicine has again opened its portals to women, and a complete course of instruction has been arranged for them at the Royal College of Surgeons; already the pioneers of what it is expected will be a large army of female students have been engaged for two months in the study of anatomy and chemistry.

Dr. Gunning's Donation.—The liberality of Dr. Gunning, of Rio Janeiro, has given an impetus to original work in the University and Colleges of Physicians and Surgeons.

The Royal College of Physicians.—The Royal College of Physicians has determined to found and maintain an institute for medical observation and research, which will be open to Fellows, Members, and to such others as its managing committee may permit.

Post-Graduate Course.—A post-graduate course of instruction in more recent methods of investigation and therapeutics was given in September and October in Edinburgh, which was largely attended by graduates and qualified men. Its success was unequivocal, and intra-mural and extra mural teachers combined and worked loyally to conduce to this result.

Fever Hospital and Clinical Instruction.—Thanks to an enlightened Public Health Committee and to the untiring efforts of the Medical Officer of Health (Dr. Littlejohn), a well-equipped fever hospital has been provided, and arrangements have just been made for systematic clinical instruction in fevers to be given to students.

The University.—In the university there are no changes to record in the professorial body. As regards the students, however, we have to notice the continued usefulness of the Representative Council, and the success which attended the efforts of the students themselves in raising by a fancy fair about £10,000 towards establishing a Students' Union. By a substantial majority they elected for a second term of office Lord Iddesleigh as Lord Rector; his opponent was Sir Lyon Playfair, a former professor of the university. Two of the professors in the university have received the honour of knighthood from Her Majesty, Sir William Turner and Sir Douglas Maclagan, and the latter has just received the additional honour of re-election for a second term of office as President of the Royal College of Physicians. By the liberality of Lord Rosebery and others two important lectureships have been endowed in connection with the chair of Natural History, namely, one on the Philosophy of Natural History and the other on Embryology; Mr. Romanes has been appointed to the former and Mr. Brook to the latter.

Direct Representation on the Medical Council.—The profession in Edinburgh did not put forward a candidate from their own school for the General Medical Council, but the successful candidate, Dr. Bruce, received a considerable amount of support from them.

Medico-Chirurgical Society.—In the Medico-Chirurgical Society the most noticeable feature of the year was a paper read by Mr. Lawson Tait and the discussion which took place on it.

Medical Staff Corps.—The Edinburgh University Medical Staff Corps has gone on successfully and is in a state of efficiency.

Royal Infirmary.—In the Royal Infirmary, on the surgical side, the principal change to be noted on the staff is the retirement of the senior surgeon, Dr. Joseph Bell, whose term of office expired two months ago. He has been succeeded by Dr. John Duncan, by whose promotion Dr. P. H. Maclaren has now got wards. The death of Dr. Angus Macdonald created a vacancy which was filled up by the appointment of Dr. Halliday Croom as physician for diseases of women, while Drs. Berry Hart and Barbour were appointed assistant physicians in the same department. Messrs. Caird and Hodsdon were appointed assistant surgeons, and Mr. Skene Keith special assistant to Dr. Thomas Keith in the ovariotomy department.

Abuse of Medical Charities.—An important movement is going on in Edinburgh with regard to the overlapping of charities, and it is earnestly to be hoped that attention will be given to the abuse of medical charities.

Small-Pox.—At South Queensferry, a few miles to the west of Edinburgh, small-pox broke out among the workmen employed at that gigantic undertaking, the Forth Bridge. It not only attacked many of them, but spread through the burgh of South Queensferry, and became so rife that it was necessary to establish a hospital-ship. Slighter outbreaks was observed in some towns on the east coast of Scotland, and in some cases these were clearly traceable to the imports from Russia. With these exceptions there has been no serious epidemic of contagious or infectious disease.

Rabies.—The occurrence of some cases of rabies, and the large number of stray dogs, induced the authorities in Edinburgh to engage in a crusade against wandering dogs; and, by regulations somewhat similar to those employed in London, the danger and nuisance were abated.

Ambulance Movement.—The ambulance movement has taken deep root, and has spread throughout Scotland; and in most of the principal towns the instruction has been extended to the police.

Small Hospitals and Convalescent Homes.—We have also to notice the number of cases in which localities have provided, or are about to provide, small hospitals, and, in some cases, convalescent homes, such as at Gilmerton, Hawick, and Musselburgh.

Obituary.—Death has not been very busy during the past twelve months among the profession in Edinburgh and its neighbourhood, but the loss of Dr. Angus Macdonald was a heavy blow to the Edinburgh School, and a sore bereavement to his many friends and pupils; while we have also to chronicle the demise of Dr. Sidey, Dr. Dunsmure, and Dr. Balfour, of Portobello.

GLASGOW.

The University.—The Extra-mural Schools.—Extension of University Teaching.—Post Graduate Courses.—Combe Lectures.—Ambulance Lectures.—Health of Glasgow.—Lochfyne Disaster.—Meeting of the British Medical Association in 1888.—Direct Representation on the Medical Council.—Obituary.—New Hospital for Women.

In Glasgow and the West of Scotland the past year has been marked by a very considerable amount of activity in directions more or less interesting from a medical point of view.

The University.—The University continues to exhibit the prosperity which has so markedly attended it for the past fifteen years. The buildings which fifteen years ago were opened for work, and which were supposed to be ample for many generations, are already too small for the students, who come up annually in ever-increasing numbers, in almost every department. From the medical department especially, the demand for increased accommodation comes with urgency. But, although new buildings, costing something like £15,000, have been erected during the year, or are likely soon to be, the money having been provided by various generous donors, these are all for special and specified purposes, and none are available for purposes of extension. The movement for a chair of Pathology has not yet borne fruit, and the professors of Physiology, Zoology, and Botany are still dependent on the length of their private purses for the due equipment of their laboratories. The students will soon have at their disposal, for the purposes of their Union, a magnificent building, at present in course of erection, due to the generosity of a yet unknown benefactor. But the minds of the authorities are anxiously concerned about the question of the resources for the annual maintenance of the building, and even now anticipate a new annual claim upon their already restricted income. No changes have this year occurred in the teaching staff of the Medical Department, though new professors fill the chairs of Church History and Naval Architecture. For the latter, accommodation is now to be found in the new lodge, built of stones from the front of the old College in High Street, and erected at the expense of the Clyde shipbuilder, Mr. Pearce, M.P., who obtained the stone owing to the demolition of the remains of the old College by railway extension. The election of a parliamentary representative for the Universities of Glasgow and Aberdeen took place in the Bute Hall of Glasgow University on July 2nd, when James A. Campbell, Esq., of Stracathro, was returned unopposed. The threatened University reform has been agitating the professorial breast more deeply than usual this past year. Some of the reformers have for years back been disturbing the peace of the General Council of the University. This year, Dr. McVail boldly attempted to enlist the sympathies of the Council in his effort to get the Medical School of the Royal Infirmary erected into a college of the University, but failed. A deputation of directors of the Royal Infirmary secured the favourable ear of the then Secretary for Scotland, the Earl of Dalhousie, but the members of the Council proved less impressionable.

The Extra-mural Schools.—The Extra-mural Schools are carrying on a rather precarious existence, in marked contrast to the condition of affairs in Edinburgh. Anderson's College has reached a crisis in its history. The scheme of a Technical College for Glasgow, uniting the resources of Anderson's College, the Young Chair of Technical Chemistry connected with it, the College of Science and Arts, and Allan Glen's Institution, has been approved and sanctioned by Her Majesty. Under its operation, the Medical School of the College is to receive £5,000, wherewith to go and found a new home for itself. If, within a limited term of years, this has not been done, the money reverts to the Technical College. Those connected with Anderson's College Medical School are, therefore, engaged in settling on a site for the school, and very wisely are seeking ground in the neighbourhood of the Western Infirmary. But £5,000 is a small sum with which to equip a medical school fitted to give a thorough medical training. It is feared that, unless more money can be raised, to enable physiological and pathological laboratories to be fairly well endowed, the prospects of Anderson's College Medical School securing many students are small. At present, some of the classes, notably that of the practice of medicine, are well attended. If this School is moved further west, the Western Infirmary School will scarcely be able to maintain a separate existence. The Royal Infirmary School has really excellent accommodation and equipments, but a terrible lack of students. The reason alleged is the impossibility of getting men to study there so long as the monopoly of examination remains with the University; hence the attempt to get the Infirmary erected into a college of the University. The truth, however, seems to be, that there is a much smaller number of students coming to Glasgow of the class that

used to come from the English country districts. Victoria University, and such new institutions, have caused this diminution.

Extension of University Teaching.—A University Association has been formed in Glasgow for the purpose of extending university teaching to the masses of the people, and in general to follow out aims similar to those of the University Extension Scheme in operation in the East of London. Premises of a very modest kind have been secured in the East of Glasgow, in the neighbourhood of the Royal Infirmary and the Old College, and there the Association will soon begin work. The experiment of post-graduate courses of lectures was tried in Glasgow this autumn; but though the lecturers were Professor Gairdner, Dr. Coats, and Dr. Newman, a mere handful of auditors came to listen to their prelections.

Combe Lectures.—The Combe Lectures on Physiology to teachers, begun a couple of years ago in Glasgow by Dr. Andrew Wilson, were given this year as usual, and were largely attended by teachers. The subject was the "Nervous System and its Work." This new system of popular instruction on physiology and hygiene is a systematic course of lectures by one lecturer, is much preferable to the occasional lectures of different teachers, and ought to do an infinitely greater amount of good.

Ambulance Lectures.—Ambulance lectures are in great demand, and seem to be relished alike by the fashionable dame and the hard-working artisan. Classes for ladies are now held in several quarters of Glasgow. Queen Margaret College for Ladies gives a course, there is another in Dennistown, and others at Pollokshields and Partick. In Paisley, Greenock, Ayr—indeed, in most of the larger towns in the West—ambulance courses of instruction have been successfully carried on.

Health of Glasgow.—The health of Glasgow would have compared very favourably with former years, but for a sudden outbreak of scarlet fever in August, which continued on till nearly the close of the year. Various circumstances connected with the outbreak led Dr. Russell to call special attention to the recent pamphlet of the Local Government Board on milk-scarlatina. Scarlet fever has, indeed, largely prevailed in Scotland this past autumn, the outbreaks being, in many cases, almost co-incident with the reopening of the public schools. Dr. Russell has this month completed his review of the Vital Statistics of the City of Glasgow by the publication of the third and final part. We shall have the pleasure of giving, in a future number, a general summary of this laborious and valuable work of Dr. Russell's. At Greenock, typhus fever was very prevalent in the beginning of the year, eight cases coming from Port Glasgow, which has no fever-hospital of its own. In something like six months, no fewer than fifty-nine cases of typhus had come from the same locality to Greenock. From Annandale an outbreak of diphtheria has been reported. The agitation for the purification of the Clyde has not yet produced much result. A public meeting, called for the purpose of inducing the citizens to take up the question themselves, failed, the meeting simply deciding to leave the matter in the hands of the corporation. Meanwhile, the Town Council is re-considering the question; but whether their consideration will issue in any practical work remains doubtful.

Lochfyne Disaster.—At Lochfyneside a disaster occurred, at the end of September, on the occasion of a monster blast. The foul gas accumulated within the quarry, and a large number of excursionists who entered to view the result of the blast were overpowered, and several died before assistance could be rendered. Altogether seven persons died, and several others were seriously ill for many days. A Government investigation took place, and a report has been issued, finding no one responsible for the accident or its results.

Meeting of the British Medical Association in 1888.—The medical profession of Glasgow and the West of Scotland have decided to invite the British Medical Association to Glasgow in 1888, and a large and influential committee has been appointed to carry out the arrangements.

Direct Representation on the Medical Council.—The election for a direct representative of the profession in the General Council of Medical Education excited comparatively little interest in the West, in spite of the fact that a local surgeon, Dr. Morton, of Glasgow, was a candidate; and the election of Dr. Bruce, of Dingwall, has given rise apparently to no considerable feeling of any kind.

Obituary.—Death has this year cut off two of the oldest and most esteemed members of the profession, Drs. Scott Orr and Ebenezer Watson.

New Hospital for Women.—In the early part of the year a new charitable institution was opened in Glasgow, the Samaritan Hospital for Women, of which Mr. J. S. Nairn is surgeon, and from it a case of successful extirpation of the uterus for cancer was reported in March. The continuance of the commercial depression has, however, seriously affected the ordinary annual income of the existing institutions, and none has felt this more seriously than the Royal and Western Infirmaries, though they have, in the course of the year, been the recipients of numerous and valuable bequests.

ABERDEEN.

Aberdeen Medical School.—Medical Officer of Health.—Royal Infirmary.

Aberdeen Medical School.—The prosperity of the Aberdeen Medical School continues uninterrupted. Its numbers have shown a marked increase during the present year, and its character as a thoroughly hard-working and practical school has been fully maintained. There have been some changes in the professorial staff of the Medical Faculty. Professor Stirling, early in the year, accepted the chair of physiology at Owens College, and the vacancy thus caused at Aberdeen was filled by the appointment of Dr. McWilliam, Assistant Professor of Physiology at University College, London, a former student of Aberdeen University. About the same time Professor Stephenson became dean of the Medical Faculty in succession to Professor Brazier, whose services for a quarter of a century, as secretary, and latterly as dean, will long be held in grateful remembrance by medical graduates of the University. The beginning of the winter session was marked by a melancholy event, quite unprecedented in its character, which cast a gloom over the university, and caused profound regret to the whole medical profession in the north-east of Scotland. Dr. Alexander Dyce Davidson, Professor of Materia Medica, died suddenly while lecturing in his class-room at Marischal College. The chair thus vacated has not yet been filled; the duties are being discharged in the meantime by Professor Matthew Hay. Dr. Frank Ogston, well known in the city, and long assistant to the Professor of Medical Jurisprudence in the university, has gone to New Zealand, having been appointed to the chair of medical jurisprudence at Dunedin College, Otago.

Medical Officer of Health.—The city of Aberdeen has, in course of the year, lost the services of Dr. W. J. Simpson, its able and energetic medical officer of health, who has gone to take up similar duties at Calcutta. His place at Aberdeen has been filled by Dr. Theodore Thompson.

Royal Infirmary.—The Special Inquiry Committee at the Royal Infirmary has finished its work, and Professor Struthers has been thanked for his services as its chairman. He has since retired from the Committee of Management. Some changes have occurred in the staff. A new post of assistant-physician has been created, and Dr. Blaikie Smith, formerly chloroformist, has been elected thereto. His place as chloroformist has been taken by Dr. Mackenzie Booth. The office of ophthalmic surgeon (vacant by the death of Professor Dyce Davidson) has been filled by the appointment of Dr. Mackenzie Davidson. Plans for the enlargement and improvement of the Royal Infirmary have engaged the earnest attention of its management during the year; and now the project recently advocated by the Lord Provost, of making the infirmary improvement a celebration of Her Majesty's Jubilee, has been cordially taken up, and gives good hopes of its early realisation. A sum of £20,000 to £24,000 is necessary for the purpose. It has been resolved to endeavour to obtain a new Infirmary Bill to incorporate the Royal Infirmary and the Lunatic Asylum.

MEDICAL EVENTS OF THE YEAR IN IRELAND.

Medical Education and Examinations: The Conjoint Scheme.—The Royal University of Ireland.—The Royal College of Surgeons.—The King and Queen's College of Physicians.—The Academy of Medicine.—Direct Representation on the General Medical Council.—The Public Health.—Changes in the Staff of the Dublin Hospitals.—Obituary.

Medical Education and Examinations: The Conjoint Scheme.—Probably the most important event as regards medical education and examination that has occurred in Ireland for many years was accomplished last October. In the adoption by the King and Queen's College of Physicians and the Royal College of Surgeons in Ireland, of a scheme for constituting a conjoint examining board in Ireland by these corporations, a result has been at last arrived at which, judging from the collapse of four or five previous efforts to accomplish so desirable a union, was looked upon as almost hopeless. The impetus given by recent legislation, however, and the example of the sister Colleges in England, had a good effect in stimulating this union, which, we trust, will be for the benefit of the profession and

of the Colleges. The scheme was submitted to the General Medical Council on the last day of its recent meeting. The Council, however, declined to consider it until after January 1st, 1887, on the ground that it was then an expiring body, and not in a position to pass a measure of such importance. The proposed scheme is on the same lines as those of the English Conjoint Board, and the Apothecaries' Hall of Ireland is excluded from it. This exclusion of the Apothecaries is one of the points which caused the collapse of some of the former attempts at a combination of the Colleges. The majority of the Fellows of the College of Physicians are understood to be much more opposed to the admission of the Apothecaries into the scheme than are the Council of the College of Surgeons. It is a matter of grave doubt, however, whether, under existing circumstances, it would not be more judicious to include the Apothecaries, and allow them to examine in materia medica and practical pharmacy, rather than run the risk of the Hall obtaining assistant examiners. If, in the event of their exclusion from the conjoint board they should succeed in doing so, they might admit candidates to an examination sufficient for full qualification under the Medical Act, after an incomplete and unsatisfactory curriculum, and at a low fee. In that way an additional and unnecessary licensing body would be formed which might possibly damage the cause of medical education, and would compete injuriously with the Colleges themselves. In any case, each of the Colleges has appointed three of its Fellows as a committee of management, which is at present hard at work in preparing examination rules, suggestions as to text-books, a syllabus of studies, and several other matters in connection with the examinations, for report to the Colleges. Until the report has been presented the Colleges postpone fixing a date for the commencement of the scheme.

The Royal University of Ireland.—The Royal University of Ireland has progressed most satisfactorily during the year, and is giving indications of becoming a real teaching university. It sustained a severe loss by the death of its Chancellor (the late Duke of Abercorn) and two eminent members of the Senate; but it is gratifying to know that the places thus vacated have been filled by so distinguished a nobleman as His Excellency the Earl of Dufferin, Viceroy of India, and by two members of our own profession so well known as Mr. Thomson, of Dublin, and Dr. Whitla, of Belfast. Dr. Lyndham, Professor of the Practice of Medicine in Queen's College, Galway, has lately been elected a Medical Fellow of the University. We alluded in the JOURNAL of May 29th to certain allegations as to the method of conducting the oral medical examinations, which were referred to a special committee of the Senate for consideration and report. We have not heard whether any report has been made, but neither have we heard of any complaints with reference to the last examinations. It may therefore be concluded that any causes of complaint, if such existed, have been removed. A most important addition to the University has recently been completed. This consists of a massive pile of buildings, comprising a dissecting-room, 120 feet long by 30 feet wide, with an extremely lofty roof of varnished pitch pine, fitted with every necessary appliance; also a physical laboratory, 90 feet long by 30 feet wide; and a magnificent chemical laboratory, with separate compartments for the accommodation of eighty students. There are also two large halls, one for physiology, and the other for histology, both of which, as well as all the other departments, are splendidly lighted, and supplied with hot and cold water, warm water pipes, etc. The lavatories are most perfect, and near them is a large and well-appointed smoking-room for the use of the students. In connection with the University, it may be mentioned that a "Graduates' Reform Association" has recently been formed, the main purpose of which is stated to be "to make the Senate and the Convocation more representative of the mind and thought of the Irish nation." For this and other equally cogent reasons, no doubt, Mr. T. P. O'Connor, M.P., has been put forward by the Association as a candidate for the vacant Senatorship. There are three other candidates for the post, namely, Professor Stephen O'Sullivan, of Cork, Dr. McMordie, of Belfast, and Major FitzGerald; and the contest will probably be a close one. The honorary degree of M.A.O. was, at the last public meeting of the Senate, bestowed on Dr. H. Macnaughton Jones, of London, in recognition of his services to the University and of his professional position.

The Royal College of Surgeons in Ireland.—In the proceedings of the Royal College of Surgeons, there has been little to note during the year. On May 27th a new museum to receive the collection of casts presented to the College of Surgeons by Mr. Butcher, was opened with much ceremony by his Excellency the Lord-Lieutenant the Earl of Aberdeen; and at the same time a statue of Surgeon Dease, one of the founders of the College, was unveiled by Lady Aberdeen. The occasion was made more memorable by also publicly conferring the Honorary Fellowship of the College on M. Pasteur, Sir Joseph Lister, Bart., Professor Huxley, Sir Spencer Wells, Bart., Mr. John Marshall, and, "last, but by no means least," Sir James Paget, Bart. In the evening, there was a banquet in the College, at which the President, Sir Charles Cameron, was honoured by the presence of His Excellency, His Serene Highness Prince Edward of Saxe Weimar, the Duke of Abercorn, the Lord Mayor, Sir James Paget, and a distinguished and numerous company. Mr. Stokes, Professor of Surgery in the College, succeeded Sir Charles Cameron as President in June, and subsequently, a few days before the Lord-Lieutenant's departure from Ireland, accepted a knighthood from him. Dr. Corley was elected Vice-President, and will, in the ordinary course, become President next June.

An interesting *History of the College and of the Irish Schools of Medicine, including numerous Bibliographical Sketches and a Medical Bibliography*, by Sir Charles Cameron, was published at the expense of the College during the year. The work is dedicated to Mr. Matthew O'Reilly Dease, D.L., to whose generosity the College is indebted for the above-mentioned statue of his grandfather, Mr. Dease, and for defraying the expenses of erecting the Butcher Museum, etc. In the history of the College the year was also notable for the circumstance that in it a woman was for the first time admitted as a surgeon on the roll of the College. The lady—Mrs. Mary E. Dowson—had previously obtained the licences of the King and Queen's College of Physicians to practise medicine and midwifery.

The King and Queen's College of Physicians.—In the College of Physicians, Dr. James Little was elected President on St. Luke's Day (October 18th), in succession to Dr. Cruise. Dr. C. E. FitzGerald, Oculist to the Queen in Ireland, and Dr. Neville were elected Fellows of the College.

The Academy of Medicine.—The progress the Academy of Medicine has made has been most gratifying. It is now in its fifth session, and the work its various sections and sub-sections have done during the year is very encouraging. The annual volume of *Transactions* is a production which reflects credit on its editor, Mr. William Thomson, and on the Academy. His Excellency the Earl of Aberdeen, when Lord Lieutenant, honoured the President, Dr. Robert McDonnell, F.R.S., with his company at an official dinner at his private residence.

Direct Representation on the Medical Council.—Dr. George H. Kidd, ex-Master of the Coombe Lying-in Hospital, and an ex-President of the Royal College of Surgeons (Ireland) was, as our readers know, the successful candidate for the post of direct representative of the practitioners of Ireland on the General Medical Council. The number of voting papers issued was 2,671, of which 531 were not returned at all, and 55 were returned through the dead-letter office. Dr. Kidd polled 911 votes, being a majority of 297 over Dr. Jacob. Dr. Jacob's majority over Dr. Laffan was 419, and Dr. Laffan scored 34 more votes than Dr. McMordie.

The Public Health.—In the last quarter of 1885 there was an exceptionally low zymotic death-rate in Ireland, and this satisfactory state of things continued, to a great extent, through the first three-quarters of the present year. In Dublin, during the first two quarters of the year, there was great freedom from typhus, enteric fever, and scarlet fever. The deaths from zymotic diseases were 118 under the average for the first quarter of the previous ten years, and 206 below the average for the second quarter for the same period. Whooping-cough was, however, very prevalent; and, owing in great measure to pulmonary complications, due to the severe and variable weather, proved extremely fatal. It constituted 52 per cent. of the total mortality from zymotic diseases for the first quarter of the year. In the second quarter, the general death-rate in Ireland was below the average rate for the corresponding quarter of the previous five years. There was no marked prevalence of any zymotic disease, and the total mortality from the principal diseases of this group yielded a rate lower than that for any quarter since details regarding causes of death were first included in the quarterly returns. During the third quarter, the state of the public health was also very satisfactory. The general death-rate was low, both absolutely and comparatively, being below that for any quarter since the third quarter of 1882; and the total mortality from the principal zymotic diseases, although in excess of that for the preceding three months—a result due to the prevalence of diarrhœa in some districts, which is usual in the third quarter of the year—was below the average. Scarlet fever became prevalent in Dublin towards the end of the third quarter, as did, also, enteric fever to a less extent; but, with two exceptions, the weekly death-rate from zymotic disease, in the present quarter, has, so far, been lower than the average for the corresponding week of the last ten years. There have also been numerous important changes in the Public Lunacy Service during the year, which have been noticed in our columns.

The Dublin Hospitals.—There have been changes in their visiting staff of three of the Dublin hospitals. Messrs Lentaigne and Chance have gone from Jervis Street Hospital to the Mater Misericordiæ Hospital, to which also Dr. T. Murphy has been appointed a Physician. Mr. Myles and Mr. F. Conway Dwyer have been elected to succeed Messrs. Lentaigne and Chance as Surgeons to Jervis Street Hospital. At St. Vincent's Hospital, Mr. Tobin, formerly Assistant-Surgeon, has been promoted to succeed Dr. Mapother, appointed Consulting Surgeon; and Mr. Gaffney has been given the Assistant-Surgeoncy.

Obituary.—Fortunately there have not been many losses by death among the working members of the profession in Dublin to deplore this year. The obituary notices we have published were chiefly those of men who were personally better known to the past than to the present generation, but whose reputation will long be cherished among Irish chemists, obstetricians, and philanthropists. James Apjohn, Evory Kennedy, Henry Grattan, and Sir John Lentaigne, were men of whom any country might be proud. All these, as well as the kindly and esteemed Thomas Darby, of Bray, were octogenarians or septuagenarians. But Mr. Kilgarriff and, quite recently, Dr. Henry, were both taken away by, we believe, the same form of malignant disease in the prime of their lives. We have also to record the sudden and unexpected death, on the 19th instant, of Dr. Lyons, D.L., late M.P., and Crown representative for Ireland on the General Medical Council.

OBITUARY FOR 1886.

DURING the past year, it has been our melancholy duty to chronicle the death of many men much honoured by the profession. Perhaps the most prominent name is that of the well-known surgeon to Guy's Hospital, Mr. J. Cooper Forster, who had been President of the Royal College of Surgeons in 1884; he had held the surgical appointment at Guy's Hospital for twenty-six years, and, when he retired, received a valuable testimonial from his old pupils. Another well-known name is that of Mr. Francis Mason, whose genial presence has been much missed in London. The sudden death of Mr. Royes Bell removed a careful and conscientious teacher. Two surgeons who had devoted their attention to ophthalmology have passed away—Mr. J. C. Wordsworth, who had almost retired from the ranks of active practitioners; and Mr. J. F. Streatfeild, who was cut off in the midst of active practice. It is no exaggeration to say that the untimely death of Dr. Walter Moxon, a man of most original mind and singularly striking parts, cast a gloom over the whole profession; the work which he had heretofore done, at once sound and brilliant, gave promise of future contributions which can ill be spared. Almost in the same words might we mention the death of Dr. T. R. Lewis, of Netley, whose valuable researches on filaria and other parasites in India had earned for him an extensive reputation, which it was but reasonable to hope would have grown in width and depth during the many years of life which seemed to await him. Not thus need we speak of some of the veterans of the profession who have joined the great majority: of Dr. Frederick Farre, of London; Dr. Henry MacCormac, of Belfast; Dr. Evory Kennedy, of Dublin; Dr. Austin Flint, of New York; Mr. Gillott, of Sheffield; Mr. W. Bousfield Page, of Carlisle; Dr. Sidey, of Edinburgh; Dr. Sutro, consulting physician to the German Hospital, London; Mr. William Pearse, of Plymouth; Mr. Darby, of Bray; Dr. William Cumming, of Edinburgh; Dr. James Apjohn, professor of chemistry in Dublin University; Dr. Richard Grattan, better known as a politician than as a physician; Dr. James Dunsmure, of Edinburgh; Dr. John Grigor, of Nairn and of Rome; Dr. Eben. Watson, of Glasgow; Dr. Norman Chevers, C.I.E.; Dr. Ogilvie Forbes; Mr. George Busk, F.R.S.; Dr. R. J. Mann; Dr. Spencer Thomson; Mr. Samuel Gaskell, for seventeen years a commissioner in lunacy; Dr. Robert Nairne, for a quarter of a century a commissioner in lunacy; Dr. Wynn Williams, the obstetrician; Dr. Storrar, the chairman of Convocation of the University of London; Dr. Scott Orr, of Glasgow; and, last but not least, Dr. Gavin Milroy, of whose services to sanitary science the remembrance will be perpetuated by the annual lectures which will be delivered at the Royal College of Physicians. Dr. Alexander Dyce Davidson, professor of materia medica in the university of Aberdeen, and an ophthalmic surgeon of eminence, died suddenly in his prime; Dr. Alfred Wiltshire, physician accoucheur to St. Mary's Hospital, and Dr. Angus Macdonald, physician, and Dr. John Bishop, assistant surgeon to the Edinburgh Royal Infirmary, must also be numbered among those taken long before their life's work was done. Dr. Kelburn King, of Hull, and Dr. Brönner, of Bradford, like some of those above mentioned, though they had earned the right to rest by forty years of active work, were yet overtaken by death while still in harness; but Mr. Sampson Gamgee and Dr. James Wakley were men still in the prime of life. In Dr. T. Spencer Cobbold we have lost one of the few English physicians who made a special study of helminthology; his death, at the comparatively early age of fifty-seven, is a distinct loss to that department of medical science. To these names must be added those of Dr. Walter Fergus, for thirty-seven years medical officer of Marlborough College; Dr. R. D. Lyons, some time M.P. for Dublin, and a Member of the General Medical Council; and Dr. Aitken, of Rome, who have joined the great majority during the last few weeks.

PROVIDENT AND BENEVOLENT INSTITUTIONS FOR THE BENEFIT OF THE MEDICAL PROFESSION.

Medical Sickness, Annuity, and Life-Assurance Society.—A retrospect of the last year would hardly be complete which failed to include a reference to the progress and remarkable success of the Medical Sickness, Annuity, and Life-Assurance Society, which furnishes to medical men the opportunity of providing weekly sickness-pay during periods of disablement, together with annuities in old age and life-assurance on favourable terms. This Society is wholly conducted by unpaid managers, selected by the members from their fellow-members of the medical profession. Last year we were able to report an accumulated reserve fund of upwards of £7,000. During the present year, over £1,600 has been paid for sickness claims, and £300 on account of members' deaths. The premium income amounts to about £8,000 a year, and an addition of over £5,000 has been made to the reserves, which will shortly amount to over £14,000. The remarkable economy of management has allowed a considerable sum to be added to the credit of the Society, the expenses of management having been considerably below the actuarial estimate.

The cases provided for during the year included ten cases of severe accident, and others of minor injury, as well as numerous examples of severe temporary illness involving complete disablement from practice, and one or two of permanent disablement occurring in the prime of life.

An important extension has been made of the benefits of the Society by the construction of a new table, which provides for the return of a large part of the annuity payments in cases where the beneficiary does not live to the period at which his annuity would commence. Of this new table a very large number of persons have availed themselves.

The extension of this Society will do much to place members of the profession in a position of independence, and to enable them to provide against the unforeseen misfortunes of accident, severe illness, and premature death, which are otherwise the cause of so much misery, and which so frequently form the groundwork of pitiful appeals, which but imperfectly meet the worst extremities of poverty and distress. The growing prosperity and great extension of this Society is a source of warm congratulation. Its financial stability has long since been assured without any addition to its membership, but in the interests of the whole profession and of individual members it is very desirable that its membership should grow until it includes all the members of the profession who are not absolutely protected against "the slings and arrows of outrageous fortune." No such means of self-help has as yet been provided in any other profession, and it is creditable to the practitioners of medicine that they have been able—not without some self-sacrifice—to originate, develop, and carry on with complete success, an institution so much needed and of such wide-reaching and beneficent influence. The Chairman of the Society is Mr. Ernest Hart; the Vice-Chairman, Dr. Ord (St. Thomas's); the Treasurers, Mr. S. Sibley and Mr. Noble Smith; the Trustees, Mr. Hart, Dr. Ord, Mr. J. R. Upton, and Sir T. Spencer Wells. The management of the Society is entirely unpaid, with the exception of the Secretary, Mr. C. J. Radley, 26, Wynne Road, Brixton, S.W., of whom all particulars can be obtained.

British Medical Benevolent Fund.—The past year has marked an eventful epoch in the history of the British Medical Benevolent Fund, inasmuch as it has attained the 50th year of its existence. Founded in 1836 for the relief of medical men, their widows, and children, it began its useful career by relieving, by means of grants, two persons in 1836-7. This, the Jubilee year, will see upwards of 180 applicants relieved by grants; while, in addition, some sixty old people, all more, and some very much more, than sixty years of age, have been relieved by annuities of £10 or £20, to say nothing of the vast number indirectly assisted by these grants and annuities. A banquet, held in celebration of the jubilee, at the Holborn Restaurant, in July, under the presidency of Sir James Paget, resulted in an addition of £3,500

to the funds; of this, £500 has been used in grants, and the balance, together with £300—a legacy from a late member of the Committee—has been funded, and the interest is available for annuities. The effect of the Jubilee Celebration has been disastrous to the donation fund; so much so that the Committee, at the November meeting, was compelled to postpone the consideration of one-half the cases before them, simply because the purse was empty. The Committee deplores this, and confidently appeals to the benevolence of the profession to remedy so painful a state of affairs. The work of this charity is undertaken gratuitously by medical men. The grants are made without canvass or publicity, after careful investigation, and administered in the way best calculated to assist the wants of applicants. The annuities are an unspeakable comfort to those who have reached old age and have, either from sickness or misfortune, made no adequate provision. Mr. George Field is the Financial Secretary.

Society for the Relief of Widows and Orphans of Medical Men.—This Society, founded in 1788, relieves those widows and orphans of its deceased members who may need assistance. All legally qualified members of the profession, residing within a radius of twenty miles from Charing Cross, are eligible for proposal, yet it is surprising how few members of the profession avail themselves of the benefits of the Society. The annual subscription of two guineas secures to the widows and orphans of members substantial assistance should they be left unprovided for. In spite of public advertisement and private circulars addressed to all within the limits of the Society, the number of members has been gradually decreasing for some years; out of over 4,000 who might become members, only about 360 have joined. This year, owing to the increasing demands on the funds, and a falling off in subscriptions and donations, a present at Christmas could not be made to the widows and orphans in receipt of grants. During the year, 63 widows, 6 orphans, and 3 orphans on the Copeland Fund, have received grants from the Society, a sum of £2 714 15s. having been distributed among them. Five fresh widows have been taken on, 4 have died. The number of members has decreased, owing to 11 deaths and 5 resignations, while only 5 new members have been elected. The offices of the Society are at 53, Berners Street, W. (Mr. J. B. Blackett, Secretary).

Royal Medical Benevolent Fund Society of Ireland.—This society, which was founded in the year 1842, was "intended to be neither a benefit society nor an assurance club; but, strictly speaking, a Benevolent or Charitable Institution, founded and promoted for the express purpose of assisting our professional brethren when struggling under the pressure of disease or other calamity. It likewise proposed, under circumstances of peculiar urgency and distress, to administer relief to the widow or family of a professional man, who may have been deprived of the support and affection of a husband or parent." Since 1848 (the first annual distribution), £32,287 have been spent in mitigating dire distress. At the 48th annual meeting of the society, held on June 7th, the chair was taken by Dr. J. Magee Finny, Vice-President of the King and Queen's College of Physicians. The Report stated that during the year £185 had been distributed among medical men, £932 among their widows, and £86 among orphans, leaving a balance in hand of £135. The Committee feel the very great value of the society, and regret that, owing to want of more general support from the members of the profession they are unable to give adequate relief to all the urgent cases that annually apply for their aid. Mr. Arthur H. Benson, M.A., F.R.C.S.I., 42, Fitzwilliam Square, Dublin, is the Acting Secretary, and to him all communications should be addressed.

The Royal Medical Benevolent College, Epsom.—The Royal Medical Benevolent College, Epsom, has had a good financial year, owing in great measure to the very successful festival held in May, under the presidency of Sir Andrew Clark, Bart., when the collection announced exceeded £4,000. The annual subscriptions also have improved. At the usual elections in May four pensioners and twelve foundation scholars were admitted; two of the pensioners and seven of the scholars were candidates whose cases were recommended by the Committee of Examination as being especially urgent. There have been no alterations in the laws or regulations of the College during the past year, but some important proposals are now under the consideration of the Council. The Society has had to regret the loss of two valued members of the Council, Dr. Harvey K. Owen and Mr. J. W. Eccles. Dr. Owen has left money by his will for the establishment of a scholarship of £50 a year for the benefit of a foundation scholar, or other orphan of a medical man, who, on leaving the College, is about to pursue his studies with a view to graduation, and of a perpetual presentation at the school of St. Anne's Society for the orphan daughter of a medical man.

BRITISH MEDICAL ASSOCIATION.

SUBSCRIPTIONS FOR 1886.

SUBSCRIPTIONS to the Association for 1886 became due on January 1st; and notice is hereby given, in accordance with By-law 5, that Branch Secretaries' subscription-accounts close on October 31st, and all unpaid subscriptions must be forwarded, after that date, to the General Secretary, 161A, Strand, London. Post Office Orders should be made payable at the West Central District Office, High Holborn.

The Issue of the BRITISH MEDICAL JOURNAL now amounts to

13,300 COPIES WEEKLY

which will be found, if tested, to show AN EXCESS of considerably more than a QUARTER OF A MILLION Copies annually over that of any other Medical Journal in Great Britain.

The British Medical Journal.

SATURDAY, DECEMBER 25th, 1886.

MEDICO-LEGAL QUESTIONS IN RELATION TO THE LAW OF DIVORCE.

THE medical witnesses in the recent case which has unfortunately occupied so much of the public attention, have been subjected to much and severe animadversion by counsel on grounds which appear to be entirely without foundation. The medico-legal aspects of the case raised some new questions of considerable importance, and the decisions in this and the previous trial establish conclusions not previously arrived at in any case hitherto tried.

The medical evidence was given throughout on both sides with great judgment and scrupulous accuracy, and appears to leave no room for cavil. From the facts stated in evidence, it appears that the husband had been operated on, both before and after marriage, for perineo-urethral fistula, due to gonorrhœa contracted in earlier life. In consequence of the condition of the husband, marriage was not consummated until four months after the ceremony. A fortnight after this consummation the wife suffered from a persistent vaginal discharge. She subsequently suffered from an attack of cellulitis. After she had recovered from this, the husband proposed to resume cohabitation; the wife refused, and ultimately appealed to the Court for protection. The trial took place in 1884 before Sir James Hannen, who, having heard the evidence of all concerned and numerous skilled witnesses, considered that she should be protected; the jury agreeing to that view, he gave judgment accordingly. This was appealed against, but the upper Court confirmed the judgment. This judgment was novel and important; it established this point, that the result of a former specific attack continuing, and being liable to injure the wife, would entitle her to a judicial separation. And it may, perhaps, be assumed that the same rule would hold good for both sexes. It appears that the judge did not require, in order to establish "cruelty," that there should be a recent specific infection. In this case, the surgeons called considered that pus would run along the urethra in cohabitation, and this they held would be fraught with danger; this view is in accordance with all modern teaching. Gynæcologists recognise that serious inflammatory attacks, and irritations of the

genital tract are liable to follow cohabitation with those who have had gonorrhœa, although all specific conditions have disappeared. This judgment is far reaching, but was, during the second trial, held to be a good one, which could not be disturbed. The question naturally arises, what length of time elapses before a specific attack (gonorrhœa) can wear itself out? This question did not affect the judgment above mentioned; but it is of much practical interest, and, in view of this judgment, important.

In the second trial, attempts were made to reopen the case, but these were checked by the judge. Another theory was, however, put forward as a possible explanation of the cellulitis; this was a suggested miscarriage shortly before the inflammatory attack. The consultant, however, who saw the case seven days after this was alleged to have taken place not only did not find the slightest evidence of miscarriage, but on the contrary found the os and cervix in accordance with the nulliparous state. Later on in the case, in dilating the cervix, it was ascertained to have the characters of congenital stenosis. The evidence on the other side was largely based on the suspicions of a nurse who *thought*, from the occurrence of severe pain and a free hæmorrhagic discharge, that a miscarriage had occurred,—a suggestion negatived by the medical evidence and easily rejected by both judge and jury. Every medical man is aware that cellulitis is very frequently associated with severe pain and free discharge, and the freer the discharge the less the internal swelling, this being nature's mode of relief. This and other phases of the case emphasize anew the risks which beset practitioners in their daily work, and the necessity for the strictest observance of professional discretion in their relations to patients of whatever position in life.

We regret to learn that, owing to ill-health, Dr. Wickham Legg has been compelled to resign the Assistant-Physiciancy and other appointments at St. Bartholomew's Hospital.

THE ANNUAL RETROSPECT.

The large amount of space occupied by the Annual Retrospect of the progress of Medicine in all its departments makes so large a demand upon our columns, that it is necessary to hold over original articles and a large number of communications until next week.

QUEEN'S COLLEGE, BIRMINGHAM.

Dr. Suckling concluded on Tuesday last his post-graduate lectures on the diagnosis and treatment of diseases of the central and peripheral nervous system. The delivery of such a course was more or less of an experiment; and judging from the large attendance, averaging over seventy-five, may be considered as a complete success. The lectures have been rendered additionally interesting, as well as instructive, by the exhibition of forty living cases in illustration of special portions of the course. Mr. Wood White, who demonstrated the use of the ophthalmoscope and perimeter in the diagnosis of nervous diseases, also showed a number of illustrative cases; and, after the last lecture, a demonstration of pathological specimens bearing upon the subject of the course was given. The success of this course will probably lead to its repetition from time to time.

TESTIMONIAL TO DR. EDWARD WATERS, OF CHESTER.

At the meeting of the Council of the Lancashire and Cheshire Branch, held at the Medical Institution, Liverpool, on Wednesday, December 8th, 1886, the following resolutions were unanimously adopted: (1) That a testimonial be raised to Dr. Edward Waters, of Chester, in recognition of his earnest devotion, through many years of self-sacrifice to the cause of internal medical reform: (2) That in accordance with the foregoing resolution, subscriptions to a testimonial fund be forthwith invited, to carry out the proposal. (3) That the members of the Council of the Lancashire and Cheshire Branch of the British Medical Association be, and are hereby appointed as a Committee (with power to add to their number), to raise a testimonial fund, and give effect to the preceding resolutions. The first meeting of the Waters Testimonial Fund Committee took place at the Medical Institution, Hope Street, Liverpool, on Wednesday, December 22nd, at 5 P.M.

SOCIETY OF APOTHECARIES.

At a Court of Assistants of the Society of Apothecaries, held on Tuesday last, Mr. R. Brudenell Carter was elected the representative of the Society on the General Council, under the provisions of the Medical Act of 1886. In electing Mr. R. Brudenell Carter as their representative, the Society has chosen a gentleman who is not a member of the Governing Body, nor even a Member of the Society, but only one of their Licentiates, and they could not have paid a greater compliment to their Licentiates than by adopting such a course. The Society has received up to the present time, from nearly 3,000 of their Licentiates, the most cordial approval of the action taken by the Society in endeavouring to form a combination with the two Royal Colleges, and the strongest expression on the part of the Licentiates of their wish to support the Society in the assertion of its rights and privileges. The Universities of Oxford and Cambridge, as might have been anticipated, have intimated that they are unable to combine with the Society; and so, likewise, has the Victoria University. The Universities of Durham and London have, as yet, given no final decision.

DEATH OF DR. AITKEN, OF ROME.

We deeply regret to hear of the death of Dr. Aitken, of Rome. This well-known and accomplished physician had for many years held a leading position in Italy, and was recognised as one of the ablest representatives of English medical science and practice on the continent. He was a favourite pupil of the late Sir James Simpson, and a most distinguished graduate of the University of Edinburgh. Dr. Aitken has for many years been suffering from a heart affection, the gravity of which was well known to him, and which involved the necessity for great precaution and abstinence from exertion. He continued, however, almost up to the last, to carry on the practice from which the requisitions of a large number of patients, who profoundly confided in his skill and kindness, made it difficult for him to withdraw, and to which he was deeply attached by his scientific tastes and predilections. Dr. Aitken was accomplished, not only in his profession, but as an artist and archæologist. Few Englishmen of cultivated tastes, who have spent any time in Rome, but have been indebted to him for many acts of hospitality and kindness, for much pleasant social intercourse, and kindly introductions to the artistic and scientific world in Rome, in which he held an enviable position. To all his medical friends he was an ever helpful, learned, and delightful guide; in him we lose a valued personal friend, a correspondent and regular contributor of many years' standing; our readers will miss the contributions of an able, well-informed, and accomplished writer, whose services were always at their disposal when occasions of interest arose. Dr. Aitken was a man of ample fortune, and spent the summer in travel and retirement. Of late years, in his visits to England, he has been less seen in professional circles than formerly, but his premature death will be felt none the less by a large circle of friends as a severe loss. He is succeeded, at Rome, by Dr. Edmonston Charles, whom he had lately associated with him in practice, feeling himself quite unequal to its burdens. Dr. Charles, who was formerly in practice in India, and subsequently at Cannes, had removed to Rome at Dr. Aitken's request.

SCOTLAND.

INFANT MORTALITY IN GLASGOW.

As the result of an inquiry into the vital statistics of Glasgow during the past six years, the medical officer of that city finds that "the mere fact that a child is born out of wedlock doubles the chances of death within a year of birth." In other words, out of 1,000 legitimate children born, 142 die before they reach their first birthday; while for illegitimate children, the corresponding figures are 277. This is the experience of other cities; indeed, in some the comparison is even more startling. But the Glasgow officer of health makes a grave charge. He speaks of the "fatal facilities" for obtaining certificates of the cause of death; and it is said that the death-roll of infants on the friendly societies' list is extremely heavy, especially of illegitimate infants.

IRELAND.

PROPOSED TESTIMONIAL TO DR. ARCHIBALD H. JACOB.

THE preliminary meeting to make arrangements for the proposed testimonial was held in the College of Surgeons in Ireland last Saturday. Dr. Corley, Vice-President of the College, took the chair. The following executive officers were unanimously elected:—Honorary Treasurers—Professor Edward Hamilton, 120, Stephen's Green, and Dr. Purcell, 71, Harcourt Street. Hon. Secretaries—Professor E. D. Mapother, 6, Merrion Square; Dr. John H. Chapman, 122, Pembroke Road. A committee was formed (with power to add to its number) from members of the profession in Dublin and the provinces, who had offered to promote the movement. It was agreed that there should be no limit to the amount of subscription, it being understood that the smallest subscription from provincial practitioners would be thankfully received.

ULSTER HOSPITAL FOR WOMEN AND CHILDREN.

THE sale of work in aid of the above institution, which may now be regarded as an annual event, was recently held in St. George's Hall, Belfast. The special object of the effort of this year is to clear off a debt of £300 incurred by recent alterations and improvements in the hospital. The hall was beautifully arranged a a gipsy-encampment. The Rev. Dr. Porter, President of the Queen's College, occupied the chair, and there was a numerous attendance. The sale was declared open by Mrs. Blakiston-Houston. Much of the work exhibited was very tasteful and artistic.

BRITISH GYNÆCOLOGICAL SOCIETY.

IN compliance with a unanimous resolution passed by the Society on December 8th, moved by the President, seconded by Dr. Granville Bantock, the Report of the Inquiry Committee of the Liverpool Medical Institution (concerning the practice of the Liverpool Hospital for Women) was referred to the Council, who have reported in the following terms:

"The Council have to report that upon such details of the report as are of a purely local character they do not propose to express any opinion, but they regret that the Committee did not see their way, with such an exceptional opportunity at their disposal, of expressing opinions which would have been of general use to the medical profession. The Council are very strongly of opinion that the time which had elapsed in the instance of all the patients whose cases were inquired into was not long enough to enable a complete and conclusive statement concerning them to be made. At the utmost this time could not have been more than twenty months, and from this point it diminished to about nine months. It must be borne in mind that, in all such cases, the ailment is of a chronic nature, and, therefore, unlikely to receive immediate relief; and, as in the instances of other operations (such as amputations, lithotrity, etc.), a much longer period, often three years, is required for a completion of the cure. The only other point which requires comment, in the opinion of the Council, is contained in the last paragraph of the Inquiry Committee's report. This paragraph recommends that the work of special hospitals for women should be greatly restricted in a direction which has, up to the present, been recognised by universal custom and practice as legitimately within their province. Operations upon the female breasts must certainly be regarded as an integral part of the surgery of the genito-urinary system.

"Concerning operations on the liver, spleen, kidney, and other abdominal viscera, the answer to the Committee's recommendation is simple and emphatic. Where were these operations before the establishment of special hospitals? In the hands of general surgeons they were not even attempted, and no satisfactory measure of success has attended efforts in this direction up to the present moment in any general hospital. The mere diagnosis of such cases requiring surgical interference is difficult, often impossible before exploration, and, when met with, their treatment is therefore far more likely to be successful at the hands of men who are, by daily experience, familiar with all the exigencies of abdominal surgery. The Council, therefore, must ask the Society to record an emphatic protest against the recommendation of the Liverpool Committee to limit the sphere of work which it is the chief aim and objects of this Society to further."

ASSOCIATION INTELLIGENCE.

COUNCIL.

NOTICE OF MEETING.

A MEETING of the Council will be held in the Council Room, Exeter Hall, Strand, London, on Wednesday, the 19th day of January next, at 2 o'clock in the afternoon.

FRANCIS FOWKE, *General Secretary.*

161A, Strand, December 16th, 1886.

NOTICE OF QUARTERLY MEETINGS FOR 1887.
ELECTION OF MEMBERS.

ANY qualified medical practitioner, not disqualified by any bye-law of the Association, who shall be recommended as eligible by any three members, may be elected a member *by the Council* or by any recognised *Branch Council.*

Meetings of the Council will be held on January 19th, April 13th, July 13th, and October 19th, 1887. Candidates for election by the Council of the Association must send in their forms of application to the General Secretary, not later than twenty-one days before each meeting, namely, December 29th, 1886, and March 24th, June 23rd, and September 29th, 1887.

Candidates seeking election by a Branch Council should apply to the Secretary of the Branch. No member can be elected by a Branch Council, unless his name has been inserted in the circular summoning the meeting at which he seeks election.

FRANCIS FOWKE, *General Secretary.*

COLLECTIVE INVESTIGATION OF DISEASE.

INQUIRIES are being pursued on the following subjects

DIPHTHERIA, THE ETIOLOGY OF PHTHISIS,
THE VALUE OF HAMAMELIS, THE VALUE OF PURE TEREBENE.

Memoranda on the above subjects, and forms for communicating observations on them, may be had on application.

The Inquiries on OLD AGE, CANCER OF THE BREAST, and the CONNECTION OF DISEASE WITH HABITS OF INTEMPERANCE, are now closed.

A Report on the CHOREA Inquiry has been prepared by Dr. Stephen Mackenzie; and will be published in the BRITISH MEDICAL JOURNAL as soon as the printing can be completed.

A Report on CENTENARIANS, prepared by Professor Humphry, was published with the JOURNAL of December 11th; a full Report on OLD AGE will follow.

Reports are in preparation upon the Inquiries made into ACUTE RHEUMATISM, DIPHTHERIA, CANCER OF THE BREAST, and HABITS OF INTEMPERANCE, and a Supplementary Report on PUERPERAL PYREXIA. All the above will be published in the JOURNAL as soon as completed. Tables of the Chorea and Acute Rheumatism cases will be published in separate form.

The Returns made to the GEOGRAPHICAL INQUIRY are being tabulated for report.

Application for forms, memoranda, or further information, may be

made to any of the Honorary Local Secretaries, or to the Secretary of the Collective Investigation Committee, 161a, Strand, W.C.

BRANCH MEETINGS TO BE HELD.

GLOUCESTERSHIRE BRANCH.—The next ordinary meeting will be held at the Gloucester Infirmary, when Dr. Batten will give his presidential address, on Tuesday, January 18th, at 7.30 P.M.

METROPOLITAN COUNTIES BRANCH: EAST LONDON AND SOUTH ESSEX DISTRICT.—The next meeting will be held, by the kind invitation of Dr. Mickle, at Grove Hall, Bow, on Thursday, January 20th, at 8.30 P.M. The chair will be taken by Cornelius Garman, Esq. Dr. Mickle will demonstrate a number of patients illustrating various forms and phases of insanity and general paralysis of the insane. Dr. C. R. Walker will show a patient suffering from locomotor ataxy, with perforating ulcer of the foot.

OXFORD AND DISTRICT BRANCH.—The next general meeting will be held on Wednesday, January 26th, 1887. Members who wish to read papers or show cases are desired to send notice of such intention to one of the honorary secretaries, on or before January 18th.—Dr. DARBISHIRE, 60 High Street, Oxford; W. L. MORGAN, Esq., 42, Broad Street, Oxford.

CORRESPONDENCE.

THE CAMBRIDGE CHOLERA FUNGUS.

SIR,—In No. 247, vol. xli, of the *Proceedings of the Royal Society*, just published, there is a preliminary report on the pathology of cholera Asiatica by Messrs. C. Roy, J. Graham Brown, and C. S. Sherrington, in which these gentlemen describe and figure the occurrence, in the tissue of the intestinal mucous membrane of persons dead of cholera Asiatica, of hyphæ, or mycelial threads and "granules." Messrs. Vines and Gardiner, we are told, declared these to be chitridiaceæ. We are further informed that these chitridiaceæ were found by Messrs. Roy, Brown, and Sherrington in the intestinal mucous membrane of the twenty-five cases of cholera they have examined, as also in the kidney and in the blood-vessels of some of these cases. I have no hesitation in saying that I consider these statements are based on error. What these gentlemen have seen and described is nothing less or more than the hyphæ, or mycelial threads of common mould (probably aspergillus), which, during preserving the material, have grown from the free surface into the tissues.

I possess a large number of specimens made of the diseased intestine, lung, kidney, liver, and skin of various animals and man, in no way connected with cholera Asiatica; in many of these I find the exact appearances described and figured by these gentlemen—viz., mycelial threads of precisely the same size and appearance as those above mentioned. They are seen to penetrate from the surface, where they form a copious dense mycelium, into the depth to various degrees. I possess sections through the mucous membrane of the intestine of the calf, of the mouse, of the guinea-pig, and of man, in which these hyphæ have penetrated as deep as the submucous tissue; in the lymphatics of this part they were very abundant. Similarly, I have specimens of the lung of calf, cow, and guinea-pig, where the growth of the mycelial threads can be traced from the pleural surface into the lung tissue, in the lymph vessels of the interlobular septa they are very numerous, and possessed of those knob-shaped outgrowths figured and described by Messrs. Roy, Brown, and Sherrington. I have also specimens of the ulcerated skin of calf and cow where these hyphæ can be traced as deep as the subcutaneous tissue. Into the kidney and the mesenteric lymph glands they also penetrate, but less than in the above organs, probably owing to the greater density of the tissue. Now in all these instances these tissues had been preserved during and over the summer months; they were examined after three or more months' preservation, and the sections were stained in methyl blue. But I must state also that the same tissues had been examined fresh and after a few weeks' hardening, and in none of them had any mycelial growth been present. It is a fact, as is pointed out by Messrs. Roy, Brown, and Sherrington, that methyl-blue brings the threads out more easily and better than other aniline dyes. There can be absolutely no doubt about the identity of the Cambridge chitridiaceæ with the hyphæ of the common mould found in the sections of non-choleraic specimens. What Messrs. Roy, Brown, and Sherrington describe as "granules" connected by delicate filaments are in most instances filaments and granules seen in optical or real transverse section; with careful, fine adjustment of the microscope this can be without difficulty ascertained. Messrs. Roy, Brown, and Sherrington assume that their "chitridiaceæ" have been overlooked by others who have examined cholera sections, because methylene blue had not been used. This assumption is entirely wrong, because methylene blue, as Löffler's (or alkaline) solution, and in other modifications, had been used by many investigators. While in India I have largely used it for staining sections fresh and after a few days' to after a few weeks' hardening, and I know as a positive fact that the German commission have in Egypt, in India, and after their return to Berlin largely used this dye. But in not one single case have they, or have I, found anything of mycelial threads, either in the intestinal mucous membrane or in any other organ. The only difference between Messrs. Roy, Brown, and Sherrington on the one hand, and all the other investigators on the other, is this, that while the former kept their material bottled over the summer (*vide* their report, p. 177), the latter examined theirs fresh, or after short and careful hardening.

That this is the real explanation of the difference of our results is proved by the following:—A bottle containing bits of choleaic intestine preserved by me in Calcutta and brought over to England was opened many months after; sections were made of the intestine and stained in methylene blue. On the free surface of the mucous membrane was found a dense plexus of mycelial threads of common mould, from which threads of various thickness had singly grown into the tissue to the depth of the submucous tissue.

Of the same choleraic intestine numerous sections had been made in Calcutta, fresh and after a few weeks' hardening; these had been stained in methylene blue, but in none of them is there any trace of mycelial threads. I have these sections at present in my possession, and while they show that there is a complete absence in the mucous membrane of mycelial threads, the others—viz, those made of the same intestine and after the same method, but after having been kept bottled for some months' show beautiful mycelial threads pervading the mucous membrane through all depths. These threads, in their course, thickness, mode of branching, in the character of the bud-like sprouts—in short, in all their morphological character—are unmistakably identical with the hyphæ found in specimens of the non-choleraic intestine, lung, skin, kidney, mesenteric glands preserved, as stated above, over the summer.

In conclusion, I wish to say that I shall be most happy to place at the disposal of Messrs. Roy, Brown, and Sherrington, as also of Messrs. Vines and Gardiner, the materials or sections mounted and stained of the various non-choleaic tissues, in which are present the mycelial threads of common mould, identical with the Cambridge cholera fungus.—Your obedient servant,

E. KLEIN.

94, Philbeach Gardens, Earl's Court, S.W., December 18th, 1886.

OBITUARY.

WALTER FERGUS, M.D.

THE vast amount of good work done, the untiring energy and unremitting care bestowed on many, call for more than a passing notice of the death of the late Dr. Fergus, for thirty-seven years the valued and trusted medical officer of Marlborough College.

Dr. Fergus was born at Newcastle-on-Tyne in 1819, and educated at King's College, London, and at the University of Edinburgh, where he graduated as M.D. in 1842. Having obtained the diplomas of M.R.C.S. Eng. and L.S.A. in 1843, he was elected house-surgeon of the Staffordshire General Hospital in 1844, a post which he resigned only on being appointed to Marlborough College in 1849. This was practically the first appointment of its kind, no other public school having a resident medical officer. The value of the appointment was soon apparent; scrupulously punctual and methodical in a degree, he gave his undivided attention to the whole establishment. Boys and staff alike, and all who sought his aid, found a kind sympathetic friend and adviser. He enjoyed the perfect confidence of the Council of Marlborough College, and the successive head masters. Failing health compelled him reluctantly to resign his post in the early part of this year. The uniform work of medical officer, even to a large school, naturally somewhat restricted general practice, but he always kept himself well read in the scientific work of the day. He was a not infrequent contributor to the medical Press, and his opinion on the subject of public school life in its sanitary relations was highly valued. In the sick room he was at his best; here the patient had not only the competent adviser, but the kind and tender nurse.

Dr. Fergus had endeared himself to a large circle of friends by many acts of kindness, and by the interest he took in the parish of St. Peter, and Marlborough generally. He was pre-eminently a Christian man, and devoted himself to every good work; was most charitable to the poor, and his loss will be regretted by all who knew him.

He died almost suddenly at Ryton-on-Tyne on December 8th. His

end, though sudden, was not unexpected by himself, for he had expressed an opinion, a short time before, that he would not live long. He was buried at Marlborough on December 14th.

ROBERT DYER LYONS, M.D., D.L., F.R.C.P.I.

WE have to record with regret the unexpected death, on Sunday last, at 1 A.M., of this well-known member of our profession. A short time after leaving his residence, in Dublin, on the previous Friday morning, he was suddenly struck down with right hemiplegia, when walking through Molesworth Street. He became at once aphasic, and never made any rally.

Dr. Lyons was in his 61st year. He was a native of Cork, of which city his father, Sir William Lyons, was twice mayor. He graduated in Medicine in the University of Dublin in 1848, and devoted himself to the study of anatomy and microscopy—a subject at that time only in its infancy. At the outbreak of the Russian war, he was appointed Pathologist in Chief to the British army in the Crimea. The result of his observations was published in an official Report (Blue-book) on the Pathology of the Diseases of the Army of the East to the Minister of War. Subsequently, he investigated, with much care and enthusiasm, the Lisbon epidemic of yellow fever, in 1857, and also reported officially in a Blue-book on that subject. After his return from the East, Dr. Lyons was appointed Physician to Jervis Street Hospital, and Professor of Practice of Medicine and Pathology to the Catholic University of Ireland. The latter appointment he held up to the time of his death; but he left Jervis Street Hospital on being elected Physician to the House of Industry Hospitals, on the resignation of the late Sir Dominic Corrigan, Bart.

In 1858, Dr. Lyons published a *Handbook of Hospital Practice*, a second edition of which was issued in 1864; and in 1870, his *Treatise on Fever* appeared. He also contributed a few papers on medical subjects to the *Dublin Journal of Medical Science*; but, although his works were the result of evident labour and research, they somehow, like his speeches, seemed to lack spontaneity and conviction, and both consequently made but little impression on his readers or his hearers. In 1880, he was elected, on Liberal principles, a member for Dublin, but his parliamentary success was not great, and he went out at the late dissolution. While in Parliament, he was appointed the Crown representative for Ireland on the General Medical Council, a Deputy Lieutenant for Dublin, and a Senator of the Royal University of Ireland.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

LYTHAM.—During the year 1885, the number of deaths registered in this district was 90; 46 being males and 44 females. From these, Dr. Fisher deducts 20 deaths occurring within the district among persons not belonging thereto, and who may therefore be termed "non-resident," by which is meant all persons who are not householders, and who have not resided in the district for a longer period than three months. This leaves 70, which, when calculated on the population of 4,435 persons, will give a death-rate of 15.7 per 1,000 for the year ending December, 1885. But has the health-officer taken account of deaths belonging to the district which occurred outside it in institutions or otherwise? Diseases of the zymotic class caused five deaths, all due to measles; these gave a death-rate of 1.1 per 1,000. Two deaths in the Cottage Hospital from enteric fever are excluded from the returns, as the disease was contracted at St. Anne's-on-Sea, where the patients resided. Five other members of the family died from the same fever in the house from which these two were removed, the sanitary arrangements being lamentably faulty. Only two cases of scarlet fever were reported during the year, both imported, and of a mild character.

NEWCASTLE-ON-TYNE.—In addition to a report on the vital statistics of the year 1885, Mr. H. G. Armstrong gives a review of the mortality of the decade immediately prior to the date of the recent adoption by the Registrar-General of his altered classification of diseases and other causes of death. The total number of deaths registered in Newcastle during the ten years ended December, 1883, is 34,480. The mean annual death-rate of the period, calculated on the mean estimated populations of the two years 1874 and 1883, is 24.2; or, if calculated on the enumerated population of the census of 1881, 23.7 per 1,000 living. The death-rate for 1885 was 26.0 per 1,000, but, taking into consideration the probable under-estimate of population, and applying it to the above returns, the death-rate would be 23.8 per 1,000. The most prevalent and fatal zymotic disease was measles, from which 359 deaths were recorded. Of these, 204 were in the second quarter of the year. Mr. Armstrong writes at some length on the spread of infectious diseases and the character of the preventive measures adopted. Scarlet fever, the disease of greatest prevalence, is shown to be the disease in which isolation has been most neglected. Mr. Armstrong considers that power to compel the removal of the infective sick to hospital from dwellings where isolation is impracticable, is greatly needed. The report also includes sections on two other subjects not dealt with in former issues of the series, viz., the results of the house-to-house inspection, concluded during the year; and the domestic distribution of the water-supply of the city. The statistics, especially of the last two sections, represent a great deal of work. The inspection, it is believed, includes a return for every inhabited dwelling in the City, except two, to which admission was refused.

READING (URBAN AND RURAL).—The statistical returns of these districts for 1885 are not as favourable as those of the preceding years. Dr. John Shea reports of the borough that the birth-rate has been the lowest recorded since 1874, though the infant mortality was low. Pulmonary diseases, bronchitis, pneumonia, and pleurisy were more fatal in 1885 than in any year during the above period. Measles was very prevalent, and the mortality from pulmonary complications was high. It became necessary to close some of the elementary schools on this account. Scarlet fever was also epidemic in a mild form, its very mildness aiding its extension. These were the only two forms of zymotic disease that manifested themselves in the rural district, and measles only was fatal. The town did not escape so easily. Diphtheria and enteric fever cases were reported from time to time, and small-pox was imported on three occasions. Diarrhœa of a fatal type was almost entirely absent, owing to the dryness of the season. The advantages of the provision of a cottage hospital were made manifest by the successful treatment of a few selected cases of scarlet fever. Dr. Shea anticipates from this the future erection of a fever hospital, sufficiently large for the borough. He considers that the prohibition of school attendance from infected houses, and the free distribution of disinfectants, fall far short of the advantages of early isolation. The death-rate for the urban district was 18.0 per 1,000, 0.1 higher than in 1884, and as nearly as possible the average of the past ten years. That for the rural district was 11.8 per 1,000.

MEDICAL NEWS.

UNIVERSITY OF LONDON.—M.B. Examination, 1886. Examination for Honours.

Medicine—First Class: J. W. Washbourn (Scholarship and Gold Medal), Guy's Hospital; W. J. Gow[1] (Gold Medal), St. Bartholomew's Hospital. *Second Class:* H. W. Gardner, St. Bartholomew's Hospital; R. B. Wild, Manchester and Owens College; R. Johnson, University College. *Third Class:* J. S. Hutton, St. Thomas's Hospital; A. F. Voelcker, University College.

Obstetric Medicine—First Class: H. W. Gardner (Scholarship and Gold Medal), St. Bartholomew's Hospital; R. Johnson (Gold Medal), University College; L. C. T. Dobson,[1] St. Bartholomew's Hospital; W. J. Gow, St. Bartholomew's Hospital, and J. W. Washbourn, Guy's Hospital; A. Carless, King's College. *Second Class:* L. M. Gabriel, St. Bartholomew's Hospital, J. A. Smith, St. Bartholomew's Hospital, and A. F. Voelcker, University College (equal).

Forensic Medicine—First Class: R. Johnson (Scholarship and Gold Medal), University College; J. W. Washbourn[1] (Gold Medal), Guy's Hospital; F. F. Burghard, Guy's Hospital; R. B. Wild, Manchester and Owens College; S. C. Jones, University College; G. E. Halstead, B.A., B.Sc., Guy's Hospital; A. E. Taylor, Guy's Hospital; A. F. Voelcker, University College. *Second Class:* K. N. Bahadhurji, University College; W. H. Horrocks, University College, and S. E. Prall, Guy's Hospital (equal); L. M. Gabriel, St. Bartholomew's Hospital; C. D. Muspratt, Guy's Hospital. *Third Class:* A. Carless, King's College; W. J. Gow, St. Bartholomew's Hospital; E. F. Bright, University College, and C. W. F. Young, St. Bartholomew's Hospital (equal); E. F. Trevelyan, B.Sc., St. Bartholomew's Hospital; E. R. St. Clair Corbin, University College.

B.S. Examination, 1886. Pass List.

First Division.—F. F. Burghard, Guy's Hospital; J. Elliott, B.Sc., St. Bartholomew's Hospital; E. Goodall, Guy's Hospital; G. E. Halstead, B.A., B.Sc., Guy's Hospital; F. C. Hart-Smith, University College; C. D. Muspratt, Guy's Hospital; W. G. Spencer, St. Bartholomew's Hospital; J. Swain, Westminster Hospital; J. J. D. Vernon, Guy's Hospital.

Second Division.—K. N. Bahadhurji, University College; R. Johnson, University College; A. E. Taylor, Guy's Hospital; A. F. Voelcker, University College; J. W. Washbourn, Guy's Hospital.

M.D. Examination, 1886. Pass List.

R. D. Batten, B.S., St. Bartholomew's Hospital; F. H. Berry, Guy's Hospital; E. H. Booth, Guy's Hospital; J. L. Boswell, Guy's Hospital; J. H. F. Brook, B.S., University College; F. F. Caiger, B.S., St. Thomas's Hospital; J. Calvert, B.A., B.Sc., St. Bartholomew's Hospital; E. J. Cave.[2]

[1] Obtained the number of marks qualifying for the University Scholarship.
[2] Obtained the number of marks qualifying for a gold medal.

St. Bartholomew's Hospital; C. C. Claremont, B.S., University College; E. P. Cockey, St. Mary's Hospital; C. R. Elgood, B.S., University College; R. F. Fox, London Hospital; J. P. Glover, St. Thomas's Hospital; E. W. Goodall, Guy's Hospital; C. Gross, B.S., Guy's Hospital; C. M. Handfield-Jones, St. Mary's Hospital; J. L. Hewer, B.S., St. Bartholomew's Hospital; F. Hinds, B.S., University College; H. H. Lankester, St. Thomas's Hospital; W. T. Maddison, King's College; F. W. Mott, B.S., University College; W. Pearce, B.S., B.Sc., St. Mary's Hospital; J. J. Powell (Gold Medal), University College; A. E. Price, B.S., Guy's Hospital; C. E. Purslow, Birmingham; E. Rice, St. Bartholomew's Hospital; K. R. Smith, B.S., University College; H. R. Spencer, B.S., University College; A. J. Turner, University College; L. C. Wooldridge, D.Sc., Guy's Hospital; S. Worthington, Guy's Hospital.

Logic and Psychology only.—J. W. Batterham, B.S., Westminster Hospital; A. H. Cook, University College; A. W. Dingley, University College; W. H. R. Forsbrook, Westminster Hospital; W. L. Heath, B.S., St. Bartholomew's Hospital; A. J. Jefferson, B.S., St. Thomas's Hospital; E. Shove, London School of Medicine and Royal Free Hospital; D. J. Slater, St. Bartholomew's Hospital; R. T. Williamson, B.S., Owens College.

M.S. Examination, 1886. Pass List.

Logic and Psychology only.—W. J. Roeckel, St. Bartholomew's Hospital.

Society of Apothecaries of London.—The following gentlemen passed the Examination in the Science and Practice of Medicine, Surgery and Midwifery, and received certificates to practise, on Thursday, December 9th, 1886.

Adams, Percy Targett, Ashford Road, Maidstone.
Brown, Edward Vipont, M.R.C.S., 123, Lady Margaret Road, Holloway, N.
Carey, Basil de Beauvoir, 22, Taviton Street, Gordon Square.
Challenor, William, 35, Alfred Place, Gower Street.
McLean, William Warker Laroche, "Ellerslen," Fulham Park Gardens, S.W.
Smith, Alfred Alexander, L.R.C.P.Ed., 43, Railton Road, Brixton.

The following gentlemen passed on December 16th:

Gravely, Harry, 48, Gloucester Crescent, Regent's Park, N.W.
Naumann, John Charles Francis, Woelman, near Eilenburg, Germany.
Sunder, Charles Edward, M.R.C.S., the College, Regent's Park, N.W.
Williams, John Thomas Creswick, Dolgelly, North Wales.

MEDICAL VACANCIES.

The following vacancies are announced.

BRISTOL DISPENSARY.—Surgeon. Applications by January 1st, 1887, to the Secretary.

BRIGHTON, HOVE, AND PRESTON DISPENSARY.—Honorary Medical Officer. Applications by January 3rd, 1887, to the Chairman of the Committee of Management.

BRIGHTON, HOVE, AND PRESTON DISPENSARY.—Honorary Surgeon-Dentist. Applications by January 3rd, 1887, to the Chairman of the Committee of Management.

CITY OF LONDON LUNATIC ASYLUM, Stone, near Dartford, Kent.—Assistant Medical Officer. Salary, £120 per annum, with board, etc. Applications by December 30th to H. F. Youle, Esq., Guildhall, E.C.

HOSPITAL FOR THE INSANE, Barnwood, Gloucester.—Junior Assistant Medical Officer. Salary, £100 per annum, with board, etc. Applications to Dr. Needham.

MIDHURST UNION, Sussex.—Medical Officer. Salary, £80 per annum, and fees. Applications by December 25th to the Clerk to the Guardians.

ST. MARYLEBONE INFIRMARY.—Assistant Medical Officer. Salary, £130 per annum, with board, etc. Applications by December 28th, to the Clerk to the Guardians.

UNIVERSITY OF EDINBURGH.—Examiner in Clinical Medicine. Salary, £75 per annum, and extras. Applications by January 17th, 1887, to the Secretary.

UNIVERSITY OF EDINBURGH.—Examiner in Surgery. Salary, £75 per annum, and extras. Applications by January 17th, 1887, to the Secretary.

UNIVERSITY OF EDINBURGH.—Examiner in Materia Medica. Salary, £75 per annum, and extras. Applications by January 17th, 1887, to the Secretary.

UNIVERSITY OF EDINBURGH.—Examiner in Physiology. Salary, £75 per annum, and extras. Applications by January 17th, 1887, to the Secretary.

UNIVERSITY OF EDINBURGH.—Examiner in Pathology. Salary, £75 per annum, and extras. Applications by January 17th, 1887, to the Secretary.

WORCESTER COUNTY AND CITY LUNATIC ASYLUM, Powick, near Worcester.—Third Assistant Medical Officer. Salary, £100 per annum, with board, etc. Application by January 6th, 1887, to Dr. Cooke.

MEDICAL APPOINTMENTS.

Balfour, Andrew, M.D.Ed., appointed Medical Officer of the Parish of Duddingston, Midlothian, *vice* A. H. Balfour, L.R.C.S.G., deceased.

Balfour, John Hutton, M.B., C.M.Ed., appointed Certifying Surgeon to Factories in the burgh of Portobello, N.B., *vice* A. H. Balfour, L.R.C.S.E., deceased.

Baker, John, M.B., C.M., appointed Medical Assistant to the Broadmoor Lunatic Asylum.

Dolby, J. Harrington, M.R.C.S.Eng., etc., Senior Assistant Medical Officer, Worcester County Asylum, appointed Medical Superintendent of the Berks County Asylum, *vice* R. E. Gillard, M.D., resigned.

Garland, J. P., L.K.Q.C.P.I., L.R.C.S.I., L.M., appointed Medical Officer to the North Dublin Union, *vice* J. P. Nolan, L.K.Q.C.P.I., L.R.C.S.I., deceased.

Gerrard, John, M.D., M.A., M.R.C.S., appointed Physician to the North London Hospital for Consumption and Diseases of Chest.

Goulett, C., M.R.C.S., L.R.C.P., appointed Resident Assistant to the Wolverhampton and Staffordshire General Hospital.

Grant, John, M.B. and C.M.Ed., late Assistant Medical Officer, Inverness District Asylum, Inverness, appointed Assistant Medical Officer to the East Riding Asylum, Beverley, Yorks.

Harries, J. T., M.R.C.S., L.S.A., appointed House-Surgeon to the Salop Infirmary, *vice* R. H. Russsell, M.R.C.S., L.S.A., resigned.

Harper, Alex., M.B., M.R.C.S., appointed Resident Medical Officer to the Victoria Hospital for Children.

Hawkins, F. H., M.D., appointed Physician to the North London Hospital for Consumption and Diseases of Chest.

Henry, John P., Med.Sch., B.A., M.B., B.Ch.Dub., appointed Demonstrator of Anatomy in Carmichael College of Medicine, Dublin.

Hughes, S., M.B., C.M.Edin., M.R.C.S., L.S.A.Lond., late House-Surgeon to the Royal Infirmary, Liverpool, appointed Senior House-Surgeon to the Birkenhead Borough Hospital.

Keyworth, Arthur F., L.K.Q.C.P.I., L.M., appointed Medical Officer for the Marple and Hayfield District of the Manchester, Sheffield, and Lincolnshire Railway Mutual Provident Society, *vice* John Howe, M.R.C.S., L.S.A., deceased.

Larder, Herbert, M.R.C.S., L.S.A., appointed Medical Superintendent to the Whitechapel Union, *vice* J. J. Ilott, M.R.C.S., resigned.

Lawson, G., F.R.C.S., appointed Consulting Ophthalmic Surgeon to the Hospital for Epilepsy and Paralysis and Other Diseases of the Nervous System, Portland Terrace, Regent's Park, London, N.W., *vice* White Cooper, Esq., deceased.

Lyon, T. Glover, M.A., M.D., M.R.C.P., appointed Physician to the North London Hospital for Consumption and Diseases of Chest.

Macdonald, John A., M.B., C.M.Glas., appointed Medical Officer and Public Vaccinator to the Denton District of the Grantham Union, *vice* R. Kingston, M.R.C.S., L.S.A., resigned.

Morgan, A. K., M.R.C.S.E., appointed Medical Officer of Health and Superintendent of Sanitary Hospital, Bournemouth.

Mugford, S. A., M.R.C.S., L.R.C.P., appointed Resident Medical Officer to th Kensington Dispensary, *vice* L. A. Buck, M.R.C.S., L.S.A., resigned.

Pearson, R., M.R.C.S., L.R.C.P., appointed Junior Assistant House-Surgeon to the Royal Infirmary, Hull, *vice* F. W. Pedler, M.R.C.S., resigned.

Pedler, F. W., M.R.C.S., appointed Assistant House-Surgeon to the Royal Infirmary, Hull, *vice* J. S. Collins, M.D., resigned.

Postlethwaite, F., M.R.C.S., L.S.A., appointed House-Surgeon to the Wallasey Dispensary, *vice* W. R. Etches, L.R.C.P., M.R.C.S., resigned.

Parry, R. H., L.R.C.P., L.R.C.S.Ed., appointed Resident House-Surgeon to the Glasgow Hospital for Sick Children, *vice* Dr. Moon, resigned.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 3s. 6d., which should be forwarded in stamps with the announcements.

MARRIAGES.

Fowler—Sinclair.—On December 15th, at Loirston, Kincardineshire, J. Francis Scott Fowler, Esq., M.B., of the Army Medical Staff, to Annie, second daughter of D. Sinclair, Esq., of Loirston and Altens.

Pike—Wheatley.—On December 15th, at Saint Phillip's Church, Miltown, by the Rev. E. Parke Wheatley, B.A. (brother of the bride), assisted by the Rev. S. M. Harris, M.A., William Watson Pike, Army Medical Staff, youngest son of the late William Pike, Esq., of Achill, to Sarah Louisa, second daughter of the late E. Park Wheatley, Esq., Dublin.

DEATHS.

Spicer.—On December 9th, Mary Elizabeth Lavinia, wife of R. H. S. Spicer, M.D., of North Molton, Devon, aged 61.

Walker.—On December 16th, at Peterborough, Thomas Walker, M.D. and J.P., in his 91st year.

Diaries for 1887.—We have received, from Messrs. Cassell and Co., who will in future be the publishers of the well-known Letts's Diaries, a copy of Letts's No. 31, Rough Diary or Scribbling Journal, with a week in an opening, interleaved with blotting-paper, published at 2s. 6d. This is a folio diary, with some useful features. It contains a great deal of accurate information in addition to that usually given, with one page set apart for "memoranda of things lent," the utility of which will commend itself to those who are not in the habit of keeping a separate book for the purpose. We have also received Letts's, No. 26, octavo 1s. Pocket-diary and Almanac. From a list accompanying the books, it is seen that Letts's diaries, in the hands of Messrs. Cassell and Co. are published in every variety of shape and style to meet the wants of all professions and trades.

National Dental Hospital.—At the annual dinner of the past and present students of the National Dental Hospital, held at the Holborn Restaurant, the toast of "The Medical and Dental Schools" was proposed by Mr. Arthur Underwood, who said that these schools were inextricably associated with each other, and he trusted that they would always remain so. Dr. Cunningham, of Cambridge, had already made considerable strides in arranging a scheme of special education in the University of Cambridge. He was engaged in a great crusade in which he was preceded by Mr. Fisher—a crusade which would end in placing all schools under the special and proper supervision of a dental surgeon. Mr. Pearce Gould and Dr. Cunningham responded to the toast.

OPERATION DAYS AT THE LONDON HOSPITALS.

MONDAY.....10.30 A.M.: Royal London Ophthalmic.—1.30 P.M.: Guy's (Ophthalmic Department); and Royal Westminster Ophthalmic.—2 P.M.: Metropolitan Free; St. Mark's; Central London Ophthalmic; Royal Orthopædic; and Hospital for Women.—2.30 P.M. Chelsea Hospital for Women.

TUESDAY .....9 A.M.: St. Mary's (Ophthalmic Department).—10.30 A.M. Royal London Ophthalmic.—1.30 P.M.: Guy's; St. Bartholomew's (Ophthalmic Department); Royal Westminster Ophthalmic.—2 P.M.: Westminster; St. Mark's; Central London Ophthalmic.—2.30 P.M.: West London; Cancer Hospital, Brompton.—4 P.M.: St. Thomas's (Ophthalmic Department).

WEDNESDAY ..10 A.M.: National Orthopædic.—10.30 A.M.: Royal London Ophthalmic.—1 P.M.: Middlesex.—1.30 P.M.: St Bartholomew's; St. Mary's; St. Thomas's; Royal Westminster Ophthalmic.—2 P.M.: London; University College; Westminster; Great Northern Central; Central London Ophthalmic.—2.30 P.M.: Samaritan Free Hospital for Women and Children; St. Peter's.—3 to 4 P.M.: King's College.

THURSDAY .....10.30 A.M.: Royal London Ophthalmic.—1 P.M.: St. George's—1.30 P.M.: St. Bartholomew's (Ophthalmic Department) Guy's (Ophthalmic Department); Royal Westminster Ophthalmic.—2 P.M.: Charing Cross; London; Central London Ophthalmic; Hospital for Diseases of the Throat; Hospital for Women.—2.30 P.M.: North-west London; Chelsea Hospital for Women.

FRIDAY .....9 A.M.: St. Mary's (Ophthalmic Department).—10.30 A.M.: Royal London Ophthalmic.—1.15 P.M.: St George's (Ophthalmic Department).—1.30 P.M.: Guy's; Royal Westminster Ophthalmic.—2 P.M.: King's College; St. Thomas's (Ophthalmic Department); Central London Ophthalmic; Royal South London Ophthalmic; East London Hospital for Children.—2.30 P.M.: West London.

SATURDAY .....9 A.M.: Royal Free.—10.30 A.M.: Royal London Ophthalmic.—1 P.M.: King's College.—1.30 P.M.: St. Bartholomew's; St. Thomas's; Royal Westminster Ophthalmic.—2 P.M.: Charing Cross; London; Middlesex; Royal Free; Central London Ophthalmic.—2.30 P.M.: Cancer Hospital, Brompton.

HOURS OF ATTENDANCE AT THE LONDON HOSPITALS.

CHARING CROSS.—Medical and Surgical, daily, 1; Obstetric, Tu. F., 1.30; Skin M. Th., 1.30; Dental, M. W. F., 9.

GUY'S.—Medical and Surgical, daily, 1.30; Obstetric, M. Tu. F., 1.30; Eye, M. Tu. Th. F., 1.30; Ear, Tu. F., 12.30; Skin, Tu., 12.30; Dental, Tu. Th. F., 12.

KING'S COLLEGE.—Medical, daily, 2; Surgical, daily, 1.30; Obstetric, Tu. Th. S. 2; o.p., M. W. F., 12.30; Eye, M. Th., 1; Ophthalmic Department, W., 1; Ear, Th., 2; Skin, Th.; Throat, Th., 3; Dental, Tu. F., 10.

LONDON.—Medical, daily, exc. S., 2; Surgical, daily, 1.30 and 2; Obstetric, M. Th., 1.30; o.p. W. S., 1.30; Eye, W. S., 9; Ear, S., 9.30; Skin, Th., 9; Dental, Tu., 9.

MIDDLESEX.—Medical and Surgical, daily, 1; Obstetric, Tu. F., 1.30; o.p., W. S., 1.30; Eye, W. S., 8.30; Ear and Throat, Tu., 9; Skin, Tu., 4; Dental, daily, 9.

ST. BARTHOLOMEW'S.—Medical and Surgical, daily, 1.30; Obstetric, Tu. Th. S., 2; o.p., W. S., 9; Eye, Tu. Th. S., 2.30; Ear, Tu. F., 2; Skin, F., 1.30; Larynx, F., 2.30; Orthopædic, M., 2.30; Dental, Tu. F., 9.

ST. GEORGE'S.—Medical and Surgical, M. Tu. F. S., 1; Obstetric, Tu. S., 1; o.p., Th., 2; Eye, W. S., 2; Ear, Tu., 2; Skin, W., 2; Throat, Th., 2: Orthopædic, W., 2; Dental, Tu. S., 9; Th., 1.

ST. MARY'S.—Medical and Surgical, daily, 1.45; Obstetric, Tu. F., 9.30; o.p., M. Th., 9.30; Eye, Tu. F., 9.30; Ear, W. S., 9.30; Throat, M. Th., 9.30; Skin, Tu. F., 9.30; Electrician, Tu. F., 9.30; Dental, W. S., 9.30.

ST. THOMAS'S.—Medical and Surgical, daily, except Sat., 2; Obstetric, M. Th., 2; o.p., W., 1.30; Eye, M. Th., 2; o.p., daily, except Sat., 1.30; Ear, M., 12.30; Skin, W., 12.30; Throat, Tu. F., 1.30; Children, S., 12.30; Dental, Tu. F., 10.

UNIVERSITY COLLEGE.—Medical and Surgical, daily, 1 to 2; Obstetrics, M. Tu. Th., F., 1.30; Eye, M. Tu. Th. F., 2; Ear, S., 1.30; Skin, W., 1.45; S., 9.15; Throat, Th., 2.30; Dental, W., 10.30.

WESTMINSTER.—Medical and Surgical, daily, 1.30; Obstetric, Tu. F., 8. Eye, M. Th., 2.30; Ear, M., 9; Skin, Th., 1; Dental, W.S., 9.15.

LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

COMMUNICATIONS respecting editorial matters should be addressed to the Editor, 161A, Strand, W.C., London; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the Manager, at the Office, 161A, Strand, W.C., London.

IN order to avoid delay, it is particularly requested that all letters on the editorial business of the JOURNAL be addressed to the Editor at the office of the JOURNAL and not to his private house.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL, are requested to communicate beforehand with the Manager, 161A, Strand, W.C.

CORRESPONDENTS who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with *Duplicate Copies*.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES, BE RETURNED.

QUERIES.

FREEMARTIN.

J. D. writes: This is the name given to a female calf, born as a twin with a male one. Can anyone tell me the etymology and origin of the word?

INSTRUCTION IN MASSAGE.

J. DUNDAS GRANT, M.D., would be glad to know where a lady of considerable intelligence, and of robust character and physique, could acquire the art of massage.

THE DEGREE OF M.D.

M.R.C.S., L.R.C.P.Lond., L.S.A. writes: I see you announce that the scheme favoured by the Councils of the Royal College of Physicians and the Royal College of Surgeons for obtaining a charter for granting the degree of M.D. to those who pass the examination of the conjoint board is rapidly assuming shape, etc. Can you inform me whether the degree will only be open to those who pass the conjoint board, or will it be open to practitioners like myself who have passed the M.R.C.S. and L.R.C.P.Lond. separately at the respective Colleges?

ANSWERS.

ONE INTERESTED.—The address of the Income Tax Repayment Agency is 16, Artesian Road, London, W.

DR. LOUIS J. M. CORDNER (Aughnacloy, co. Tyrone) will find an account of senile decay of the mental powers, etc., in the following: An article by Dr. Anstie, on Certain Nervous Affections of Old Persons, in the *Journal of Medical Science*, vol. xvi, p. 31, April, 1870; one by Dr. Conolly, in *Medical Times and Gazette*, vol. i, p. 489, 1858; Dr. Maudsley's *Pathology of the Mind*; and *A Manual of Psychological Medicine*, by Drs. Bucknill and Hack Tuke.

PRODUCTION OF CARBONIC ACID GAS.

A.B.—The volume of CO_2 given off from sodæ bicarb. ℥i., when saturated with tartaric acid, will vary according to temperature and pressure; but assuming that the temperature is 60° F. and the pressure is 30 inches, that the sodium bicarbonate is pure and dry, and that the troy or apothecaries ounce of 480 grains is signified by the symbol ℥j; then the volume of CO_2 given off would be 533 cubic inches, or nearly 15½ pints.

NOTES, LETTERS, ETC.

THE RIDDELL FUND.

DR. JOSEPH ROGERS, President of the Poor-law Medical Officers' Association, writes: A letter, of which the subjoined is a copy, was recently forwarded to me. It refers to a very sad story, the particulars of which had been sent to me by the unhappy man several months ago, when he wrote for my advice, which was to the effect that it was much to be regretted that he had incurred the hostility of anyone who had it so much in their power to render his professional life uncomfortable, and I trusted that he would do his best to minimise the hostility he had evoked. It would appear, however, that it was not to be so, and the unhappy man rushed into eternity under the influence of a morbidly sensitive nature. The letter was sent on to me by his wife, who informs me that she is wholly dependent on the sale of his small practice for the present means of living.

My health is too much broken to take an active part in collecting anything for the poor woman's benefit, but Mr. John Wickham Barnes, F.R.C.S., 3, Bolt Court, Fleet Street, E.C., whom I have just seen, will kindly receive and apply for the widow's benefit any monies from the well-to-do members of the profession.

[*Copy.*]

Dunsford, December 3rd, 1886.

Dear Dr. Rogers,—Before this reaches you I shall be no more. My enemies have triumphed. One of the guardians made a most unprovoked attack (and, as he afterwards acknowledged, unfair attack) upon me, and in a moment of exasperation I wrote a letter to the Board of Guardians. They forwarded it to the higher Board, and now I have been dismissed. Standing now on the brink of eternity, I solemnly repeat what I told you before, that all the persecution arose from the fact of our turning our backs on —— daughter when we found that....We never mentioned our knowledge to any outsider, but my wife left the choir. From that day till now we have been cruelly boycotted, and now ruined. It is too late to begin life again. I trust myself and my family in the hands of God Almighty. If you can do anything for my wife and family, why God bless you. And now good-bye.—Yours truly,

(Signed) R. RIDDELL.

MR. J. WICKHAM BARNES (3, Bolt Court, Fleet Street) writes: Dr. Rogers having published my name as being willing to receive contributions for the widow of the late Dr. Riddell, of Dunsford, near Exeter, I think it only proper that your readers should know something of the case they are called upon to subscribe to. About two years ago, Dr. Riddell communicated with Dr. Rogers in regard to differences between himself and his guardians, arising, as he considered, from causes foreign to his appointment. Since that time, complaints (as he said, without reason) have continually been made against him, when, in a fit of desperation, he wrote an intemperate letter to his guardians, who forwarded the same to the Local Government Board, which brought an answer requiring his resignation. The shock resulting from this letter was too great for his enfeebled and worried brain, death by strychnine being the result; but immediately before taking this, he wrote a heart-rending letter to Dr. Rogers, expressive of his inability to bear up any longer against his troubles, thanking him for former kindness, and asking him to do what he could to assist his widow and children, who are left totally destitute. Dr. Rogers, I am grieved to say, is too ill to move in the matter, and if no one else can be found better able to help the poor widow and children, I will receive contributions for them, however small the amounts, and will insert them weekly in the BRITISH MEDICAL JOURNAL, with your kind permission.

The Degree of M.D.

HOPEFUL writes: So far as I have observed, legislation involving fundamental changes is frequently, if not always, accompanied by conditions which respect and secure life interests. This is both just and reasonable. The rank and file of the medical profession are so accustomed to the pressure of hardships, that they seem to have come to regard these as inseperably associated with professional life. One of these hardships has of late years come to occupy a very prominent position. I refer to the difficulty which a great proportion of medical practitioners have had to encounter in their efforts to obtain an university degree; which, in a great many instances, they have failed to secure. In what follows I intend to confine myself to a class of practitioners who must be somewhat advanced in life, and whose number is getting "small by degrees." Allusion is here made to some who, variously qualified, were in practice about the year 1858. One reason I mention 1858 is because my principal data will be taken from the Medical Directory for Scotland for that year. There it is stated as one of the regulations to be observed in granting the degree of M.D. by the then University and King's College, Aberdeen, that "practitioners who possess a licence or diploma from any of the Royal Colleges of Physicians or Surgeons, or from the Apothecaries' Company, and who have been engaged for at least five years in the practice of medicine after the receipt of the diploma, will be admitted to examination, on producing their licence or diploma, along with satisfactory evidence of good moral character, and of having studied the classics at a university or at an academy of acknowledged reputation."

Again, the "regulations applicable to medical practitioners," in connection with what was at one time "Marischal College and University, Aberdeen," contain, *inter alia*, the following: "Practitioners may be admitted, without residence, to examination for the degree of M.D., who have held a diploma or a licence in medicine or in surgery, for at least ten years, and who produce satisfactory evidence of good moral character, and having been engaged in practice during that period."

And yet again, the University of St. Andrew's had the following as one of its "regulations:" "Fellows, Members, and Licentiates of the Royal Colleges of Surgeons of England, Edinburgh, and Dublin, of the Royal College of Physicians of London, of the Faculty of Physicians and Surgeons of Glasgow, and of the London Apothecaries' Company, are eligible as candidates for the Degree of Doctor of Medicine, on producing their diploma or licence."

It need scarcely be stated here that the two Aberdeen teaching and licensing bodies mentioned above now constitute the university of that city. Although I shall not labour under the disadvantages of having only a single qualification, under the Medical Act of 1886, yet I am one of those who suffered by the changes introduced about a quarter of a century ago, and which should have been strenuously resisted. There cannot be a doubt that we have been unjustly deprived of our rights, and that we have not only an equitable claim to be allowed, as practitioners, to be candidates for the degree of M.D. at the Universities of Aberdeen and St. Andrew's, but we ought to be treated by the authorities of these universities with very great consideration.

This is a subject which should interest not only those immediately concerned, but which demands the attention and aid of the Imperial Government, of the General Medical Council, of the Universities of Aberdeen and St. Andrew's, of the Medical Corporations, of the Medical Schools, and of all the members of the medical profession who desire to see the restoration of what should never have been taken away.

The Office of Coroner and the Medical Profession.

DR. G. E. YARROW (97, Old Street, E.C.), writes referring to the observations in the JOURNAL of December 18th, on the above subject: Permit me to say that after conferring with some electors of great influence, I decided not to pursue my canvass, firstly, because it was thought unwise to split the medical interest, and, secondly, because Dr. Macdonald appeared to have a better chance of obtaining the appointment than myself; but it was clearly understood that in the event of a vacancy being created by the division of the district, I should again offer myself as a candidate, and hope to obtain the support of my medical brethren.

"Mont Dore" at Bournemouth.

THE REV. JAMES HERBERT WAKELYN writes: The Baths at Bournemouth, hitherto known as the "Mont Dore" Establishment, have, after many changes, passed into hands under which they will be simply at the disposal of the members of the medical profession, for use at discretion, being no longer under special control, and having no resident medical officer. It is hoped that this may clear the way for their more general use for health-purposes.

Medical Providence.

DR. W. FLEMING PHILLIPS requests us to state that his present address is 18, Oxford Street, Southampton.

A Degree for London Medical Students.

A DISGUSTED M.R.C.S. writes: On November 27th the University of London published their pass list, and thirty-six candidates were successful; so that, out of the seven or eight hundred students joining the London medical schools, all who start in practice, except thirty-six, do so under the disadvantage of not being entitled to call themselves "Dr.," and sign themselves M.D., although they have been as well trained and passed as severe tests as the Scottish graduates, and have done infinitely more practical work.

This right might be obtained if the Royal Colleges and the Society of Apothecaries were united; but "if a house be divided against itself it cannot stand," let alone succeed against the opposition of the universities of the three kingdoms. But if the Royal Colleges persist in their suicidal policy, the only course would be for the Society of Apothecaries to make some private arrangement with some British or even foreign university, such as Pennsylvania or Brussels, whereby the examination for a degree can be conducted at Blackfriars. The Licentiate of the Hall would then be equipped with a M.D., a legal power to recover fees for his duties, and a right to have his degree placed on the *Register*.

I am sure the thanks of all general practitioners are due to you for the hearty way you have championed our cause in the JOURNAL.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE "BRITISH MEDICAL JOURNAL."

Seven lines and under	—	—	—	—	£0 8 6
Each additional line	—	—	—	—	0 0 4
A whole column	—	—	—	—	1 15 0
A page	—	—	—	—	5 0 0

An average line contains seven words.

When a series of insertions of the same advertisement is ordered, a discount is made on the above scale in the following proportions, beyond which no reduction can be allowed.

For 6 insertions, a deduction of	—	—	—	10 per cent.
,, 12 or 13 ,, ,,	—	—	—	20 ,,
,, 26 ,, ,,	—	—	—	25 ,,
,, 52 ,, ,,	—	—	—	30 ,,

For these terms, the series must, in each case, be completed within twelve months from the date of first insertion.

Advertisements should be delivered, addressed to the Manager, at the Office, not later than noon on the Wednesday preceding publication; and, if not paid for at the time, should be accompanied by a reference.

Post-Office Orders should be made payable to the British Medical Association, at the West Central Post-Office, High Holborn. Small amounts may be paid in postage-stamps.

SUPPLEMENT

TO THE

BRITISH MEDICAL JOURNAL.

[The annexed page, No. 17, completes the Supplement (Professor Humphry's Report on Centenarians) issued with the Journal of Dec. 11th, 1886].

DIRECTIONS TO THE BINDER.

[The Supplement, pp. 1–17, including the annexed page, to be bound at the end of the Journal for 1886, Vol. II. It is included in the Index].

SUPPLEMENT
TO THE
BRITISH MEDICAL JOURNAL:

TABLE OF THE CONDITIONS, HABITS, FAMILY HISTORY, ETC. OF CENTENARIANS,

Made from a Form of Inquiry Issued by the Collective Investigation Committee of the British Medical Association.

With Remarks and Analysis
By PROFESSOR HUMPHRY, F.R.S.

In the publication of this table it is not meant to be implied that each of the fifty-two persons positively attained to the age of 100 years. Some no doubt did so; and in eleven (two males and nine females) the age was confirmed by baptismal certificates or other records. Respecting others, there is necessarily more or less uncertainty; but these may reasonably be assumed to have reached nearly to that age. The name is given in each case; and the names are also given of the informants. These were nearly all medical men who volunteered the information which they would not have done unless they believed it to be correct, and who, in many cases, were well acquainted with the persons respecting whom they gave the particulars. The well-known pride of longevity and the tendency to exaggerate and deal with the marvellous throws some suspicion over all records of this kind, and, indeed, had well-nigh caused a revulsion to misbelief in the capacity of the human body to retain vitality for so long a period as a hundred years. Abundant well-established examples of its doing so have, however, dissipated that scepticism which, I suppose, is now held by scarcely any one. It will be observed that none of the cases here tabled range among the marvellous and startling instances we sometimes read of; not one is stated to have reached 110; one only is said to have been 108 and one 106.

Our thanks are due to the gentlemen who have been so good as to take the trouble (often considerable) to gather and give the information from which the table has been made. For assistance in compiling it, and for the analysis, I am indebted to A. Francis, M.R.C.S., of King's College, in this University. In a subsequent number I propose to offer some remarks upon the few instances which have reached me in which *post mortem* examinations of centenarians have been made; and I shall be very glad to receive any information on that head which may be sent me within the next two or three weeks.

I have a large collection of reports of persons between eighty and a hundred, which are all tabulated, and the analyses of which, with remarks, I hope in due time to publish in the Journal; but the interest attaching to a record of so many reputed centenarians will, I think, be deemed to justify the printing of this table at length.

A few reports of centenarians have come in since the table was in type, and the analysis made. Any special points arising from these must be given subsequently.

N.B.—The capital letter given in a column is the initial letter of one of the words in the heading above. Where *stout* and *spare* are in the heading, the word *stout* is indicated by "st." The horizontal line in a column indicates that no information on that detail was given, thus distinguishing from O which indicates a negative.

Though it must be granted even of the centenarian, as of all others, that he soon "passeth away and is gone," yet happily we are not obliged to admit that his "strength is but labour and sorrow." In many instances, on the contrary, he has, if not a green, yet a mellow and cheerful old age, one of happiness to himself and pleasure to others, brightened by a vivid though calm interest in the present, and unshadowed by apprehension of that which is to come. "Pay me a visit when you next come to Leamington," were usually among the words of adieu by Miss Hastings, at the age of 103, to her friends; "I shall like to see you, and hear how you are going on." There is a great moral in this; for while we are denizens in this Mammon, we are bound to make to ourselves friends of it, which is best done by a cheerful happy use of it, and by enjoying it and using well the powers and privileges it gives us; and the injunction is none the less imperative and valuable when the sojourn in it has lasted for five score years and more. Moreover, in this, as in so many other instances, the influences are reciprocal; for associated as cheerfulness and happiness are with good doing and kind feeling, they are also much dependent upon the smooth working of the several parts of a sound bodily machinery, to the healthfulness of which they in their turn not a little contribute. So long, indeed, as the body is enjoyable, and its functions go glibly and smoothly on, the tenant is commonly desirous of continuing its occupation. When it ceases to be so, when lassitude and weariness supervene, when means of communication with others are stopping, when the "*sans* everything" condition is impending, he is content to quit; and when the tenement becomes distressing or painful, he is anxious to do so. Still, though the capacities for activity and work may be passing away, and life's "iretful fever" with them, the old person may comfort himself with the reflection that a useful mission still remains in the benign influence of a serene and benevolent disposition, which calmly estimates the things of time and sense at their true value, and which, leniently regarding the shortcomings of others, gives the true crown of glory to the hoary head.

It is most satisfactory to find that the exercise—even the full exercise—of the various powers, mental and bodily, is not merely compatible with, but is conducive to, great age; that, as has been well said, "the harmonious development of the many-sided aspects of man is conducive to health and the prolongation of life," and that there need be no fear of entering heartily and actively, and with full interest and energy, into the assigned work of life, physical or mental. The body is made, not for ease and sloth, but for labour and play, for work and enjoyment, better still for enjoyment of work. Work, enjoyed as it should be, promotes health of body, and especially if stimulated by other motives than personal ambition and gain, engenders that cheerful placid frame of mind which is one of the adjuncts of centenarianism.

France has lately celebrated the centenary of a philosopher and a chemist, M. Chevreuil, who the same night occupied the President's box at the opera; and we are told that a Chinese centenarian recently passed the examination which qualified him to enter the highest academy of the Mandarins. Delightful was the account of Lady Smith, in whom a bright intelligent mind and a brisk healthy body had been in uninterrupted harmonious action for a hundred and three years, and who to the last took a lively interest in the world's political and other movements.

Among the centenarians on our own list, the intellect is stated to have been high in 11 and low in 5 only; 20 are reported as strong, 16 of average strength, and 12 only as feeble. Several were remarkable for mental and bodily activity and energy during their long lives. Many had been engaged in hard bodily toil, or mental work, or, successfully, in various occupations, and, in different ways, had played their parts effectually on the world's stage to the end of the long drama in better plight than the poet has represented them. I often wish Shakespeare had lived to give a brighter version of his seven stages, and to portray the old man not lean and slippered, but well favoured and booted, keen in life's interests, and happy in promoting the welfare and enjoyment of others. Even in the bedridden state, of which the tables give seven examples (four males and three females), one of whom had been bed-ridden for seven years, all is not cheerless. The quiet coziness, the even temperature, the freedom from exposure, and the reservation to the vital organs of nerve-energy and nutritive material, consequent on the diminished use of the muscular system contribute to prolong the lives of some feeble persons who still retain the pleasures of intellectual occupation and social intercourse, to say nothing of the enjoyment of sleep and the gratification of the appetite; and it is curious, though not unfrequently to be observed, that persistence in bed actually increases both sleep and appetite. Some aged people lie in bed in the winter; and, in the dull routine of the workhouse, many old people drift into the bedridden state.

In our tables, as usual in records of longevity, the women preponderate over the men (36 to 16), in spite of the dangers incidental to child-bearing and the diseases associated with the varying demands made, at different periods, upon the organs connected with that process. This is obviously, in great measure, to be attributed to the comparative immunity of the woman from the exposures and risks

(Continued on Page 14.)

[1] Still from chronic rheumatism, deformed from contraction of palmar fascia. [2] Born August 23rd, 1784, as stated in family Bible; died March 5th, 1886 after two days' acute bronchitis. [3] Verified by vicar of parish. [4] Remembers, and will quote a great deal of the Bible. [5] Certificate of christening dated March 1786. [6] Sharp, rather slow in comprehending question, but smart in reply; reads for hours, and mends her own clothes. [7] Born February 21st, 1784.

[1] Short walks and sitting out. [2] Sounds distinct, no murmur, very irregular, at one minute beating sixty to seventy, at another double as fast; chest resonant, respiratory sounds almost inaudible. [3] Had no illness until day before her death. [4] Some incontinence for ten years. [5] Walks daily half a mile, can walk three miles. [6] Heart and lung sounds weak, but no evidence of disease. [7] Can walk very well, and has all her faculties. [8] At 96 mended the thatch of her cottage, and was always the first home from church, being a rapid walker. [9] Abscess connected with spine leading to slight deformity in dorsal region; injured knee at 50, leaving stiffness; diarrhœa from 75 to 90; slight fevers twice in middle life; other ailments, from time to time, not definable; fractured neck of femur at 101, by a fall, on crutches afterwards. [10] Stays in bed in cold weather. [11] Walks in garden, fond of sawing firewood. [12] Goes to church twice on Sundays. [13] Heart-sounds normal, temperature 98°. [14] Works in garden, attended Hexham Market two years ago.

thoroughly recovered her strength; her brain, which had been previously very clear, failing; five days before death she had a convulsive seizure, became less clear, took less nourishment, and finally slept away." An active, temperate person, of long lived family, happy disposition, never talked about dying, always asked her friends to come and see her again, newspaper read to her every day. Says she was a remarkably small baby. [2] Very old.

to which man is subjected, as well to her greater temperance in eating and drinking, and her greater freedom from the anxieties attendant upon the world's labour and business. Still, as I have said in a former essay (BRITISH MEDICAL JOURNAL, May 9th, 1885, p. 928), there appears also to be a greater inherent vitality in the female, as evinced by the fact that, even in the first year of life, when the conditions and exposures of male and female infants are the same, the mortality of girls is less than that of boys. A somewhat larger number of boys are born, but they are more difficult to rear, so that the females soon take the numerical lead, and they maintain it with almost steadily increasing ratio to the end. It is also to be learned from the analysis of the tables that the elasticity of the thorax, as evinced by the condition of the costal cartilages, and its capacity for dilatation during inspiration, is better preserved in women than in men. In the matter of the arcus senilis, also, the woman has the advantage; but, in the condition of the arterial system, much difference is not shown.

Of the 56 women, 26 had been married, and 11 had large families; and it may be some consolation to young mothers and their friends to find that 8 of the 26 married before they were twenty—1 at 16 and 2 at 17. The dangers, happily diminishing, which are incidental to child-bearing, must not be forgotten; but, irrespective of these, the process itself and the attendants thereon do not seem to militate against longevity. Indeed, the capacity for the full exercise of this, like that of the other normal functions, is one of the qualities in those who have the other requisites for attaining to great age. One only of the married women was childless; but neither the age at which she was married nor the duration of her married life are given.

It might be anticipated, indeed, from the matrimonial tendency, and the prolific quality evinced by the tables, the average number of children born to each, whether male or female, being 6, that there would be, through inheritance, a gradual increase in the centenarian breed; and it is probable that this is the case, and that the duration of life is, from this and other favouring causes, gradually being extended. The life-period of the children we have no means of determining with accuracy, the returns being, from various causes, imperfect; but we may safely accredit them with, at least, an average longevity. It is, moreover, a point of some interest that many of the centenarians were members of large families, averaging, indeed, 7 or 8; those designated as "only children" being limited to 2. Of the 52, 41 had been married, and 11, of whom 10 were women, had remained single; but we cannot from this draw any inference as to influence of matrimony upon longevity. Possibly something may be gleaned from the analysis of the numerous reports I have received of persons between 80 and 100.

The fact that 12 of the centenarians were "first children" does not accord with the idea entertained by some persons that first children are at a physical disadvantage. The generally prevalent custom of inheritance by the first-born, and the Mosaic injunction (Exodus xii, 2) "sanctify unto me all the first-born; whatsoever opened the womb among the children of Israel, both of man and of beast, it is mine," are also scarcely in harmony with such a view. Nevertheless, some confirmation of the view is furnished by the feeling on this matter, founded, it may be presumed, on experience in racing stables, which, I have been informed, is not in favour of firstlings. In the case of one of our centenarians, the parents were first cousins.

The tables and the analyses of present and past condition yield nothing striking or even novel or unexpected, or in that respect interesting; but they are not therefore less valuable or important. The average centenarian qualities are precisely those which might have been anticipated: a good family history; a well made frame of average, stature (5 feet 8, which is rather above the average, in the male, 5 feet 3 in the female); spare rather than stout, robust, with good health, little troubled with ailments of any kind, with good digestion, regular daily action of bowels; active, capable of much exertion, with the restorative advantages of good sound sleep permitting or inducing early rising; good vocal organs; a good appetite moderately indulged, with little need of, and little consumption of, alcohol or animal food; an energetic yet placid temperament; a good intelligence; the hair holding its ground and its colour well; the organs of sight and hearing performing their functions well and long. Our centenarians afford, in short, good examples through life of the *mens sana in corpore sano*; and in by far the greater number there was a total absence of any evidence of rheumatic or gouty affection, past or present, in the joints of the hands and fingers—a condition which is not unfrequently regarded as one of the heralds of old age, and which, doubtless, like many other local maladies of which it may be taken as a sample, is often prophylactic against other more serious maladies. It seems that the frame which is destined for great age needs no such prophylactics, and engenders none of the peccant humours for which the finger-joints may find a vent. To have a vent for such humours may be good, but it is less good than to be without them. Of the eight in whom those joints were stiff or deformed, it may be observed that one (1) a man, always "drunk as much as I could, and always will do;" a second and third (6 and 21), poor women, had been subject to much exposure, and had a rough life, following the army in various parts of the world; of the case of the fourth (20) also a female, in whom these joints were stiff, we have no account of the habits. The fifth (29), a female, appears to have been a temperate person in comfortable circumstances, in whom no particular reason for the deformity of the joints can be assigned; and the same may be said of the sixth and seventh (30 and 39), except that the latter was in the habit of partaking rather freely of animal food, and also probably of the eighth (49), though we have not much information as to her past habits. It is rather remarkable that all of these, except the first, are females; of these females, three were poor, and the others in comfortable or in affluent circumstances.

Teeth.—The loss of teeth presents some interesting problems. It seems to be an associate of civilisation, partly because the varied and peculiar conditions of civilised life tend to induce it, and partly because those conditions have the effect of preserving the body beyond the limits which, under natural or uncivilised conditions, appear to have been assigned to it. Not developed till the animal begins to care for itself, the teeth fade away when it ceases to be able to do so; and, in the state of nature, life is not much prolonged beyond the period when the self-providing powers are waning. Civilisation, however, brings many external or extraneous aids and protections which carry the body on beyond what may be called the dental or natural span, and maintain it in spite of losses and changes which, to the uncivilised man, would have been fatal. Of these changes, the loss of teeth is one from the ill effects of which we obtain great immunity. Twenty-four of our centenarians had no teeth, some had been without them many years, and the average number retained was only four or five, which, in many instances, we may conclude to have been of little value. The artificial substitutes were used in so few instances, that we cannot from them form an estimate of the aid afforded by these appliances in the prolongation of life; but that they do contribute to the maintenance of health and the prolongation of life can scarcely be a matter of doubt. The teeth had disappeared, as we have before found to be the case (BRITISH MEDICAL JOURNAL, May 9th, 1885, page 929) in the upper jaw more than in the lower; but the tables do not show so much difference between the men and the women as I then marked.

It is somewhat remarkable that, though as many as twenty-eight used glasses, thirty-five, including many who used glasses, are reported to have been in the enjoyment of good sight. The occurrence of presbyopia does not seem to be associated with, or to be a prelude to, inconvenience or impairment of sight beyond that which may be corrected by glasses. These had been used by some for forty or fifty years; and in three it appears that the defect was spontaneously rectified, and that as they grew older they became able to dispense with glasses.

That the majority of centenarians are content, as we find them to be, with three meals in the day, and are moderate or small eaters, partaking of little animal food and little alcohol, is in harmony with the lowered activity of the muscular and other organs, and the consequent lowered demand upon the nutritive processes and the nutritive supply. That nevertheless the rate of the pulse, averaging 70, and that of the respiration, averaging 22, is maintained, may be accounted for by the diminished elasticity of the circulatory and respiratory apparatus. The arteries become less capable of accelerating the blood-stream, and the vital capacity of the chest is much reduced, as shown by the slight difference in the chest-girth between the state of inspiration and that of expiration.

The sleep-duration, averaging nearly nine hours, indicates also a slowness, a feebleness, of the restorative processes. Repair is tardily and with difficulty striving to keep pace with wear. We know that it is one element in the developmental law of growth and decay, that it should not quite do so in the aged frame. Up to adolescence repair has the mastery, and the body gains in weight and strength; in middle-age, repair is about equal to wear; but in later life its gradual failure, attended with diminishing weight and strength, conducts the body slowly along its normal course to dissolution. Long, good sleep, does something to put a drag on the downward course, and is a great sustainer of the aged frame. Much difference in sleep-duration is noted in the tables. In some, sleep is said to have been short and indifferent, or bad, perhaps owing to peculiar disturbing causes; but in 32 out of 44 it is said to have been good.

The maladies of these old people range themselves chiefly under the head of weakness, evinced by inability to put forth or maintain much effort of any kind, bodily or mental. Fatigue soon comes on; the muscular weakness proceeding to partial or complete loss of the use of the lower limbs, and to tremor of the upper limbs. The difficulty of penning a straight line resulting from this latter, being the cause of the smallness of the handwriting, often noticeable of old people. The weakness of the brain evinces itself in impairment of memory, in slowness of apprehension, in inability to fix the thoughts long on one thing, and the tendency, therefore, to wander from one subject to another, and to travel to and fro, which may pass on to want of control, or imbecility, or even to dementia. This last, saddest state of all, was witnessed only in two of our centenarians. Indeed, the brain in many held out as well or better than other organs—which may be regarded one of the bright rays, if not the brightest, in the centenarian landscape.

The weakness, or failing, seems to have been about equal in the several great organs, showing that these organs presented to the last that good balance of enduring strength which is so essential to longevity. The lungs are, through life, the most sensitive to atmospheric changes, as well as to alterations in the conditions of the blood. Hence, bronchitic and pneumonic affections are a common source of distress, and a frequent cause of death at all periods of life; but it does not clearly appear that the very aged are more liable to them than those less advanced in years.

In the majority in our table the action of the heart was regular, the pulse small and compressible, and evidences of arterial degeneration not manifest. In some of those who were auscultated, more or less *bruit* was heard, indicating some valvular or arterial roughness; but it made no apparent impression, and the individuals were unconscious of any defect. The slowness of micturition mentioned in two men, and the incontinence in three females, as well as the frequency of micturition in three, may also be regarded as resulting from atony, rather than from disease. Indeed, these old people had outlived the period which is most liable to prostatic and other urinary troubles. Other minor maladies and discomforts, of which we may conclude that centenarians have their share, such as the slight eczema in No. 3, and the flatulence in No. 4, have, in many instances, probably been thought not worthy of mention.

Though the majority had suffered little from illness at former periods, some up to the very end of their long life, yet it is not unsatisfactory to find that the effects of illnesses, even when severe, do not always preclude longevity. No. 1 had rheumatic fever when young, and rheumatism afterwards; No. 5 had epilepsy from 17 to 70; No. 7 had renal disease, with loss of sight, at 30, from which there was complete recovery; No. 8 had an abcess connected with the spine, a stiff knee from injury at 50, and diarrhœa from 75 to 70, besides fevers and other ailments; No. 9 had gall stones at 60; No. 10 was ten years in an asylum after a confinement; No. 11 had peritonitis; No. 12 had had fever at 25, also jaundice and small-pox; No. 13 had "bad stroke" at 60, for which she was bled, and two less severe strokes at 70. No. 18 had renal dropsy at 82, lasting for two years; No. 23 had acute bronchitis at 95; No. 29 had paralysis at 90; No. 31 had severe herpes zoster; No. 33 had rheumatic fever at 70; No. 45 had severe bronchitis at 82; No. 51 had paralysis at 7; Nos. 6, 12, 17, and 47, had fever—12 and 47 badly.

The recoveries from illness at great age, to which I have before called attention in this JOURNAL (July 12th, 1884, May 9th, 1885, and August 7th, 1886), are to be noted. We find that No. 18 recovered at 82 from renal dropsy, which lasted two years, and at 98 recovered from a large slough on the thigh, caused by a bruise; No. 23 from acute bronchitis at 95, and pneumonia and erysipelas of the head at 99; No. 33 from rheumatic fever at 70; No. 45 from severe bronchitis at 82; and No. 47 from severe fever at 84. Six had suffered injury to the hip after the age of 90. One broke the neck of the thigh-bone at 90, and one at 101, the latter so far recovering as to go on crutches.

Most interesting and important of all are the life-habits of these old people, among which, activity, out-of-door exercise, and early rising, with moderation in diet and alcohol, stand out in strong relief, and are evidently among the important factors in longevity. At the same time, we perceive that most of them may be regarded as the attributes of the well-wearing body, that is to say, they are the resultants of health, as well as the promoters of it. The healthy, vigorous body, can scarcely be otherwise than active, in one way or other; and few things tend to promote health and vigour more than activity—activity without excitement—an activity which is not forced beyond the measure of good and easy repair—an activity which does not wear the body out. The candle ought to burn briskly, and, as a general rule, at both ends, regarding the head or brain as one, and the limbs or locomotory agents as the other; but it should not burn too fast; and it may be that, in some persons, an extra rate at one end is better to be compensated by a lower rate at the other. Some persons, at least, seem to find that severe and continued brain-work is incompatible with much leg-work. Into this question, however, I will not enter.

Upon out-of-door activity, with the refreshing influence of open air, stress should be laid, for it must not be supposed that exercises and athletics in-doors, where they are much more exhausting, are a sufficient substitute, especially in the case of young and growing persons.

Such activity causes a brisk trade in the nutritive market; and the demand is pretty sure to be met by the supply, when food can be obtained. The moderation or spareness in diet, notably in the past habits of our centenarians, limiting the supply, prevents a wasteful overflooding of the market, and compels an economical and good employment of all that is brought there. Surplusage can do but harm. The body associates itself with a certain well known evil agent in finding for idle food "some mischief still to do," although, in some individuals, a drainage for unused material may be made through the intestinal or renal or cutaneous organs, which, be it remembered, were never meant to serve that purpose, and which are likely to suffer from the strain thus put upon them. In many a more deleterious vent is found in gout, bilious attacks, etc., which, at the same time, cause a temporary arrest of supply, or in graver inflammatory attacks, or the still graver malignant affections. The temperance in all things of our centenarians has, without doubt, been one great means of keeping order in their nutritive system, and preventing aberrations into morbid processes. Few more mischievous notions have found their way into common acceptance than the idea that strength is proportionate to the amount of food taken; and it is accepted and mischievous, no doubt, in a greater degree than it would otherwise be, because it rests upon the basis of truth that strength cannot be maintained without a sufficient supply of food.

The total abstainers will not fail to observe that twelve of our centenarians had been through life, or for a long period, in their ranks; that twenty took little alcohol; that this was, in the case of some of them, *very* little; and that eight were moderate. No. 8, it is true, often drank to excess on festive occasions; No. 14 was a free beer-drinker; and No. 35 "drank like a fish during his whole life," which probably means when he could, for it is added that "he could not usually get much." The exceptions, therefore, show little against the rule. It is, perhaps, scarcely less important to note that our centenarians were, for the most part, small meat-eaters.

The early rising was in many of the instances necessitated by their occupations. Still, this habit must be regarded as an associate or sequence of the healthful activity just mentioned, and of an activity pervading the reparative work which has to be done in sleep—an activity which quickly and thoroughly refits the body for its next day's work, and gives the energy, the willingness, the desire to resume it. Sleep should come quickly, be intense while it lasts, and cease quickly and completely; quite awake or quite asleep; no hovering between the two; no need of, or desire for, a little more slumber, a little more sleep. "When one turns in bed, it is time to turn out," whether rightly or wrongly attributed to the Duke of Wellington, is a saying worthy of him, and accords with the energy that contributed to make his life great as well as long.

While we thus gain more clear knowlege of the qualities for, and the adjuncts to, centenarianism, an examination of the table shows that there is no royal road to it. We see that it is attained under a variety of conditions, and that few persons can be said to be excluded from the prospect of it. With regard to certain of the important requisites, we cannot alter our position. No one can make his family history better than it is, or make his body to be wound up for a longer period than its normal life's span; but it is the duty of each to endeavour to make it cover that span, and to go as long as its appointed time. The uncertainty as to that term, as it is one of the greatest blessings of life, so should it be one stimulus to us to ascertain and to follow the means most suited for prolonging life, especially as we find the result of our investigations to be that those are the means best calculated to turn it to good account and to make it happy.

ANALYSIS OF THE TABLE OF CENTENARIANS.

By A. FRANCIS, M.R.C.S., of King's College, Cambridge.

PRESENT CONDITION.

AGE.—Fifty-two returns; average age, about 102½ years. *Males.*—Sixteen returns; average age, about 102¼ years; respective ages, 108, 105, 104, 3 aged 103, 4 aged 102, 2 aged 101, 101¼, 3 aged 100.—*Females.*—Thirty-six returns; average age, about 102⅛ years; respec-

tive ages, 2 aged 108, 106, 3 aged 105, 3 aged 104, 4 aged 103, 102½, 3 aged 102, 7 aged 101, 100¾, 100½, 10 aged 100. In 11 cases, the age returned was verified by baptismal certificates or other records; of these, 2 were males, aged 101 and 100; and 9 were females, aged 108, 106, 104, 103, 102, 101, 101, 100½, and 100.

MALE OR FEMALE.—Fifty-two returns; M. 16, F. 36.

SINGLE: MARRIED: WIDOWED.—Fifty-two returns; S. 11 (of these 10 were females), M. 5, W. 36.

AFFLUENT: COMFORTABLE: POOR.—Fifty returns; A. 3, C. 23, P. 19.

FAT: SPARE: AVERAGE.—Fifty returns; F. 9 (of these 8 were females), S. 23, A. 18.

FULL-BLOODED: PALE: AVERAGE.—Forty-six returns; F. 8, P. 14, A. 24.

STRONG: FEEBLE: AVERAGE.—Forty-eight returns; S. 20, F. 12, A. 16.

FIGURE: ERECT OR BENT.—Fifty returns; E. 25, B. 25.

HEIGHT. *Males.*—Twelve returns; average, about 5 ft. 8½ in.; one also returned as short. *Females.*—Twenty-six returns; average about 5 ft. 3 in.

WEIGHT. *Males.*—Seven returns; average nearly 138 lbs. *Females.*—Ten returns; average about 129 lbs. Respective Weights. *Males.*—182, 165, 147, 140, 120, 112, 98 lbs. *Females.*—196, 154, 140, 136, 126, 126, 120, 112, 112, 70 lbs.

VOICE.—Forty-seven returns; loud, 6; clear, 16; weak, 7; full, 3; loud and clear, 8; full and clear, 6; loud and full, 1.

HEARING.—Forty-nine returns; good, 22; indifferent, 17; bad, 9; deaf, 1.

JOINTS.—Forty-seven returns; natural, 37; stiff, 4; deformed, 3; stiff and deformed, 1; the last was stiff from chronic rheumatism, and deformed from contraction of palmar fascia; slightly deformed, 2; one of these was "from rheumatoid arthritis."

SIGHT.—Fifty-one returns; of these, 34 had good sight; 6 had cataracts, in one case unilateral, in another commencing; in 8 others, failure of eyesight was reported, apparently independent of presbyopia.

GLASSES.—Thirty-five returns; 28 used glasses, 7 did not, but of these 4 were returned as "poor," and were possibly unable to read; 6 had used them for 40—50 years, 5 for 30—35 years, 4 for 10—20 years, 2 for 4—6 years, 5 for "many years," 2 for "few years." One had used spectacles for many years, but for last twelve years had been able to read without them; another had not used them for twelve years; another "not for many years," but one "cannot now get them strong enough."

DIGESTION.—Forty-seven returns; good, 40; moderate, 7.

APPETITE.—Forty-eight returns; good, 36; bad, 2; moderate, 10.

EATER.—Forty-six returns; moderate, 25; small, 9; large, 12.

NUMBER OF MEALS DAILY.—Forty-three returns; average number rather more than 3 daily; the greatest number was 5 daily (in 1 case); the least number was 2 daily (in 5 cases).

ALCOHOL.—Forty-six returns; none 15; little, 24; moderate, 6; great deal of beer, 1.

ANIMAL FOOD.—Forty-one returns; none, 3; moderate, 10; little, 25; very little, 2; much, 1.

BOWELS.—Forty-three returns; daily, 26; alternately, 6; irregularly, 11.

APERIENTS.—Forty-one returns; rarely, 22; never, 14; frequently, 5.

DISPOSITION.—Forty-six returns; placid, 14; irritable, 8; energetic, 11; placid and energetic, 8; irritable and energetic, 5.

INTELLECT.—Forty-six returns; average, 29; low, 5; high, 11; childish for 6 years, 1. One was said to be "slow in comprehending questions, but smart in reply."

MEMORY. Recent Events.—Thirty-nine returns; good, 26; bad, 6; moderate, 7. Past Events.—Forty-seven returns; good, 39; bad, 4; moderate, 4. One "remembers and will quote a great deal of the Bible," another could "repeat about 100 Psalms correctly."

HABITS.—Forty-eight returns; active, 26; sedentary, 15; bedridden, 7; of these, 4 were males and 3 females; one, a male, had been bedridden for 1 year, and one, a female, for 7 years.

OUT-OF-DOOR EXERCISE.—Forty-five returns; bedridden, 7; none, 16; of these, one "can walk very well," another "stays in bed in cold weather;" little, 9; one of these "mended the thatch of her cottage at 96, and was always the first home from church, being a rapid walker;" moderate, 1, she "goes to church twice on Sundays;" eight walk out; of these, one "walked four miles yesterday," another "walks daily half a mile, can walk three miles," another is "fond of sawing firewood;" two still work, one of these "attended Hexham market, two years ago;" one "worked in field at 102;" one was "much out."

SMOKES.—Forty-five returns; much, 7; four of these were women; little, 2; one was a woman; moderate, 3; one was a woman; none, 32; chews, 1.

SNUFF.—Forty returns; none, 37; much, 1; this a woman who also smoked a little; little, 2, one being a woman, who did not smoke, the other a man, who smoked a little.

SLEEP.—Forty-four returns; good, 32; bad, 5; moderate, 7. *Number of Hours.*—Twenty-nine returns; average, rather more than 8½ hours; 3 slept 12 hours; 8 slept 10 hours; 1 slept 4 hours; and 2 slept 6 hours.

HOUR OF GOING TO BED.—Thirty-five returns; average, about 9 o'clock, one retired at 12 o'clock, one at 11, and 5 at 7 o'clock; 7 were bedridden.

HOUR OF RISING.—Thirty-five returns; average, about 8 o'clock; six rose at 6 o'clock, one at 5 o'clock, nine at 10 o'clock, one at 11 o'clock, and one at 4 P.M.

CHEST-GIRTH IN INSPIRATION. *Male.*—Six returns; average, 36½ inches. *Female.*—Nine returns; average, nearly 31 inches. Male and female together, average about 33 inches.

CHEST-GIRTH IN EXPIRATION. *Male.*—Five returns; average, about 36½ inches. *Female.*—Seven returns; average, nearly 30 inches. Male and female together, average about 32½ inches.

ELASTICITY OF RIB-CARTILAGES. *Male.*—Six returns; distinct, 1; indistinct, 5. *Female.*—Thirteen returns; distinct, 5; indistinct, 8.

PULSE.—Twenty-nine returns; average, 74-75 per minute. In some cases, disease of the heart or lungs was returned, and in others the pulse-rate was unusually high, and the condition of the heart and lungs was not detailed; excluding these cases, eleven in number, the average becomes 69-70 per minute. *Regular, Irregular, Intermittent.*—Twenty-eight returns; R. 24; Irr. 1; Int. 3. *Large, Small, Moderate.*—Twenty-seven returns; L. 9; S. 17; M. 1. *Compressible, Incompressible.*—Twenty-eight returns; C. 24; I. 4.

ARTERIES. *Male.*—Nine returns; even, 4; knotty, 2; tortuous and knotty, 1; tortuous, visible, and even, 2. *Female.*—Twenty returns; even, 8; tortuous, visible, and knotty, 3; visible and tortuous, 2; tortuous, visible, and even, 1; visible and even, 2; tortuous and knotty, 1; tortuous, 2; tortuous and even, 1.

ARCUS SENILIS. *Male.*—Seven returns; much, 4; little, 1; absent, 2. *Female.*—Nineteen returns; much, 5; little, 8; absent, 6.

RESPIRATION.—Twenty-four returns; average, 24 per minute. Excluding those cases, eleven in number, in which heart or lung-disease was returned, or in which the rate of respiration was high, and the condition of the heart and lungs was not mentioned, the average becomes 21—22 per minute. *Regular and Irregular.*—Twenty-four returns; regular, 21; irregular, 3.

TEETH.—Forty-two returns; 24 had none, and in 13 the teeth were specified. Amongst the 37 cases, there were 144 teeth: upper jaw, 63—incisors, 19; canines, 8; molars, 36: lower jaw, 81—incisors, 23; canines, 13; molars, 45. In five cases the number was alone given. Average (42 cases) 4—5 teeth. In one case, they "all came out whole." *Males.*—Fourteen returns; 6 had none; average 4 teeth. *Females.*—Twenty-eight returns; 18 had none; average, nearly 5 teeth. Three females had a complete set, and another had 17 teeth; one male had 24, and another 16 teeth.

ARTIFICIAL TEETH.—Thirty-eight returns; none, 34; yes, 1 (female); many years, 2 (male and female); from 50—90, 1 (female).

EVIDENCES OF FAILURE.—Thirty-five returns; none, 18; failures in 17 cases. *Heart*, 2.—In one, "sounds distinct, no murmur, very irregular, at one minute beating 60—70, and at another double as fast;" in the other, "circulation feeble, frequently sick and faint, as if she were going." *Heart and Lungs*, 3.—In one, "heart and lung-sounds weak;" in another, "pulse intermits 6 times in minute, impulse weak, slight bronchitis;" in another, "aortic regurgitation, slight bronchitis." *Heart and urinary organs*, 3.—in one, "loud systolic *bruit* at base, no appreciable interference with circulation, micturition frequent;" in another, "heart-sounds tumultuous and irregular, micturition frequent;" in another, "heart's action slightly irregular, not discernible in pulse, frequent micturition." *Lungs*, 2.—in one, "chronic bronchitis;" in the other, "cough for four months." *Brain*, 3.—Senine dementia in two cases; in one, "childish for 6 years;" in the third case, apoplexy, right hemiplegia, aphasia, and death shortly after. *Brain and Urinary*, 1.—"Aphasia for 14 days, incontinence of urine." *Urinary*, 4.—One had "some incontinence for 10 years;" in two others, micturition was slow; and in another, "incontinence."

MICTURITION. *Male.*—Ten returns; natural, 7; slow, 2; frequent, 1. *Female.*—Twenty-three returns; natural, 18; frequent, 2; incontinence, 3—in one case for 10 years.

Printed and published by the Proprietors, the British Medical Association, at their Office, No. 161, Strand, in the Parish of St. Clement Danes, in the County of Middlesex.

PAST HISTORY.

AGE WHEN MARRIED. *Male.*—Twelve returns; average, nearly 31 years. *Female.*—Nineteen returns; average, nearly 25 years.

DURATION OF MARRIED LIFE. *Male.*—Twelve returns; average, 54-55 years. *Female.*—Eighteen returns; average, 33-34 years.

NUMBER OF CHILDREN. *Male.*—Sixteen returns; average, 6-7 children. *Female.*—Twenty-one returns; average nearly 6 children. One male, and one female had no children.

FIRST, OR—CHILD OF PARENTS.—Thirty-eight returns; average, about third child. Twelve of these were "first child," and of these 2 were also the "only child." In 14 cases the size of the family was also returned; and in these the average was second-third child, and the number in the family averaged 7-8 children.

AFFLUENT, COMFORTABLE, POOR.—Forty-nine returns; A. 3; C. 28; P. 18.

STOUT, SPARE, AVERAGE.—Forty-seven returns; st. 3; sp. 28; A. 16.

DELICATE, ROBUST, AVERAGE.—Forty-three returns; D. 2; R. 28; A. 13.

HEALTH.—Forty-five returns; good, 45.

AILING.—Twenty-one returns; rarely, 19; often (male) 1; never, 1.

DIGESTION.—Forty-five returns; good, 44; indifferent, 1.

BOWELS.—Forty-two returns; good (daily), 34; costive, 6; alternate, 1; relaxed, 1.

BALDNESS.—Eighteen returns; late, 14; early, 3; none, 1.

GREYNESS.—Forty-two returns; late, 29; early, 12; none, 1.

DISPOSITION.—Forty-three returns; placid, 14; irritable, ; energetic, 10; irritable and energetic, 8; placid and energetic, 7.

INTELLECT.—Forty-six returns; average, 32; high, 10; low, 4.

HABITS.—Forty-eight returns; active, 46; moderate, 2.

OUT-OF-DOOR EXERCISE.—Forty-one returns; much, 27; little, 6; moderate, 8.

HOURS IN BED.—Twenty-nine returns; average, 7 hours; one also returned as "few hours."

HOUR OF RISING.—Thirty-three returns; average, about 6 o'clock; one also returned as "late."

SLEEPER.—Forty-three returns; good, 38; average, 5.

APPETITE.—Forty-three returns; good, 42; indifferent, 1.

EATER.—Forty-one returns; average, 27; small, 7; large, 7.

ALCOHOL.—Forty-one returns; none, 12; moderate, 8; little, 20; and one who "always drank as much as I could, and always will do," *vide* also remarks Nos. 8, 14, 35.

ANIMAL FOOD.—Thirty-five returns; moderate, 7; little, 28.

SMOKE. *Male.*—Fifteen returns; much, 7; little, 1; none, 7. *Female.*—Twenty-eight returns; much, 4; little, 1; moderate, 1; none, 22.

SNUFF. *Male.*—Fifteen returns; none, 13; "yes," 2. *Female.*—Twenty-three returns; none, 21; "yes," 1; much, 1.
